The solution from the colorimeter cell was diluted with eight volumes of water and one volume of concentrated hydrochloric acid added. The acidified olution, which is colourless, was extracted with benzene ($3 \times \frac{1}{3}$ vol.) and the combined benzene xtracts washed with water until neutral. When he Zimmermann reaction was repeated on the material extracted by benzene, the extinction corresponded to 60–95 per cent recovery of steroid; he colour appeared immediately with alkali alone and maximum intensity was obtained under Zimmermann conditions in 20 min.

When the recovered Zimmermann complexes of the separated 17-oxosteroids (approximately 5 µgm.) were chromatographed on No. 2 Whatman paper in a hydrocarbon/aqueous methanol system[1] spots could be located as dark areas by viewing in ultra-violet ight of maximum intensity in the 240 mµ region Hanovia *OX*7 filter). These areas were also revealed as purple spots by dipping in ethanolic potassium hydroxide (10 per cent w/v). The immediate appearance of the purple colour together with the absorption of ultra-violet light suggests that the *m*-dinitrobenzene s combined with the steroid on the paper chromatogram. These complexes appear to be very stable as hey were not destroyed by hot acid hydrolysis (10 per cent hydrochloric acid v/v at 100° for 15 min.) or by the subsequent washing of benzene extracts by alkali.

Table 1, which gives the R_F values of the free 17-oxosteroids and of their derivatives when run in Bush partition systems, shows that whereas in the *A* system the free compounds run faster than their derivatives, in the B_1 system they run more slowly. This diverse behaviour appears to be associated with the partition system used and not with the C_{11}-oxygen function, for the 11-oxo-aetiocholanolone derivative runs in the *A* system more slowly than the corresponding free compound.

Table 1. R_F VALUES OF STEROIDS AND DERIVATIVES ON WHATMAN No. 2 PAPER

Equilibration time, 3 hr.; running time, 4 hr.; temperature, 37°)

	Free steroid	Derivative
Bush *A* system		
Dehydro*iso*androsterone	0 32	0·23
*iso*Androsterone	0 37	0·31
Aetiocholanolone	0·43	0·33
Androsterone	0 56	0·46
11-Oxo-aetiocholanolone	0·064	0 042
Modified Bush B_1 system		
11-Hydroxy-aetiocholanolone	0·40	0·70
11-Hydroxy-androsterone	0 50	0·78
11-Oxo-aetiocholanolone	0·64	0 83
11-Oxo-androsterone	0 70	0·88

Bush *A* system: 80–100° petroleum ether (10), methanol (8), water (2). Modified Bush B_1 system: 80–100° petroleum ether (5), benzene (5), methanol (7), water (3).

R_F values calculated against sudan IV, which was used for indicating the solvent front approximately.

The Zimmermann complexes formed from 5α-androst-3 : 17-dione, 5β-androst-3 : 17-dione, androst-4-ene-3 : 17-dione and androst-4-ene-3 : 11 : 17-trione did not move from the origin in Bush *A*, B_1 or B_5 systems.

This technique has enabled us to obtain further evidence of identity of steroids isolated from blood plasma by chromatography on alumina.

We wish to express our thanks to Dr. T. F. Gallagher, Sloan Kettering Institute, New York, and to Dr. W. Klyne, Hammersmith Postgraduate Medical School, for the gift of reference steroids, and to Sir Charles Dodds for his interest in this work.

An Asymmetric Catalyst

ASYMMETRIC synthesis has hitherto succeeded only by using reagents or solvents having the asymmetric configuration.

We have been able to synthesize optically active amines and amino-acids by using an asymmetric catalyst, based on the fact that the optical activity of the biological substances originates in the asymmetric structure of the enzyme proteins.

The asymmetric catalyst was obtained by reduction of protein–palladium complex which was prepared by adsorption of palladium chloride on silk fibroin fibre.

Optically active glutamic acid, phenylalanine and diphenylethylenediamine were formed by hydrogenating their precursors, diethyl α-acetoximino-glutarate, ethyl α-acetoximinophenyl-propionate, 4-benzilidene-2-methyloxazol-5-one and α-benzildioxime, respectively, in the presence of this catalyst.

Preparation of catalyst. 100 mgm. of palladium chloride was adsorbed on 300 mgm. of silk fibroin fibre, and the complex was reduced with hydrogen in 50 ml. methanol at 50° C., 80 kgm./cm.^{2} for 1 hr.

Hydrogenation of diethyl α-acetoximinoglutarate. 10 gm. of diethyl α-acetoximinoglutarate was hydrogenated with the catalyst in 50 ml. methanol at 50° C., 80 kgm./cm.^{2}. The reaction mixture was filtered, evaporated *in vacuo*, hydrolysed for 1 hr., precipitated with hydrochloric acid, and extracted with acetone to remove organic acids. Then the product was recrystallized four times. Glutamic acid was obtained in a yield of 39 per cent. $[\alpha]^{15}_D =$ + 2·25° (c., 7 per cent in 2*N* HCl). Analysis: calculated for $C_5H_{10}O_4NCl$: N, 7·63; found: N, 7·36. This compound was identified by paper chromatography and infra-red spectroscopy. The manometric analysis (by glutamic acid decarboxylase of *E. coli*) showed the same value of L(+) content.

Hydrogenation of ethyl-α-acetoximinophenyl-propionate. 6 gm. of ethyl-α-acetoximinophenyl-propionate was hydrogenated with the catalyst in 50 ml. methanol at 70° C., 90 kgm./cm.^{2}. The reaction mixture was filtered, evaporated *in vacuo*, hydrolysed for 4 hr. with 30 ml. 10 per cent hydrochloric acid and evaporated *in vacuo* again. The residue was dissolved in 10 ml. water, decolorized, evaporated to half volume of the solution *in vacuo*, diluted with 5 ml. methanol, and adjusted to *p*H 7·0 with aqueous ammonia. After standing overnight, 1·5 gm. of phenylalanine was obtained; m.p. 261·5° C. $[\alpha]_D^{15} = +9{\cdot}25°$ (*c.*, 9 per cent in water). Analysis: calculated for $C_9H_{11}O_2N$: N, 8·48; found, N, 8·23. This compound had the same R_F value as the standard phenylalanine.

Hydrogenation of 4-*benzylidene*-2-*methyloxazol*-5-*one*. 5 gm. of 4-benzylidene-2-methyloxazol-5-one was hydrogenated with the same catalyst in 50 ml. methanol at 75° C., 90 kgm./cm.². The reaction mixture was filtered, evaporated *in vacuo*, hydrolysed for 4 hr. with 30 ml. 10 per cent hydrochloric acid. The acid solution was extracted with ether, and the water layer was evaporated *in vacuo*. The residue was dissolved in 10 ml. water, decolorized, concentrated to 3 ml., diluted with 3 ml. methanol, adjusted to *p*H 7 with aqueous ammonia. After standing overnight, 0·7 gm. of phenylalanine was obtained; m.p. 280° C. $[\alpha]_D^{20} = +12{\cdot}5$ (*c.*, 9 per cent in water). Analysis: calculated for $C_9H_{11}O_2N$: N, 8·48; found, N, 8·23. This compound was identified by paper chromatography.

Hydrogenation of α-benzildioxime. 5 gm. of α-benzildioxime was hydrogenated in 10 per cent ammoniacal methanol at 80° C., 80 kgm./cm.², with the same catalyst, and the product was recrystallized from *n*-butanol. Diphenylethylenediamine (2·5 gm.) was obtained. Analysis: calculated for $C_{14}H_{16}N_2$: C, 79·21; H, 7·60; N, 13·20; found: C, 78·05; H, 7·20; N, 12·12. $[\alpha]_D^{15} = +8{\cdot}75$ (800 mgm./100 ml. of ether); $[\alpha[_D^{15} = +431{\cdot}0$ (29·6 mgm./100 ml. of ether). (In this experiment, we observed the wide variation of $[\alpha]_D$ of diphenylethylenediamine with the concentration of the substance in diethylether.)

It appeared that the palladium adsorbed on the supporter having the asymmetric configuration was capable of catalysing the asymmetric reduction.

A New Reagent for the Determination of Thorium

Several organic acids[1–4] have been used for the quantitative precipitation of thorium. By a careful control of the *p*H value, thorium may be separated from the rare earths. The precipitate in most cases is rather of indefinite composition, and for a quantitative determination, it has to be ignited to thorium oxide and weighed. We have been engaged in investigating derivatives of cinnamic acid to see if they possess any advantages over other acids which have been employed hitherto.

It was found that *m*-nitro cinnamic acid not only gives a clear-cut separation of thorium from other trivalent rare-earth ions, but also gives a thorium precipitate of definite composition. The precipitated thorium salt is the tetra-*m*-nitro cinnamate and is one of the very few examples of precipitation of thorium as the tetravalent salt.

An alcoholic solution of *m*-nitro cinnamic acid was added to a solution of thorium salt at *p*H 2·0 or less and this was carefully adjusted to 3·8–4. The higher *p*H value is specially necessary when sulphate ions are present. Thorium came down as a granular precipitate. The precipitate was filtered, washed with hot alcohol and weighed as thorium tetra-*m*-nitro cinnamate. It was then ignited and weighed as thorium oxide. The following are typical results.

Weight of thorium tetra-*m*-nitro cinnamate (gm)	0 1135
Weight of ThO_2 (by calculation) (gm.)	0 02997
Weight of ThO_2 (by ignition) (gm.)	0 0299

Thorium may therefore be determined by a direct weighing of the precipitate instead of by igniting, as has been done hitherto.

The same experimental procedure may be followed for separation of thorium from trivalent rare earths; if, however, the proportion of the rare earths is preponderantly high, a double precipitation may be followed.

Tetravalent ions like titanium, zirconium, cerium (ic), etc., are also precipitated by this reagent and would thus interfere.

Further details will be published elsewhere.

Recording Differential Thermogravimetric Balances

In recent years, interest has been revived in the application of the thermogravimetric technique for the characterization of inorganic and organic compounds, and for studies concerning their thermal decomposition process. Several types of automatic balances have been developed—some of them now being commercially available—to give recorded curves of the cumulative weight-loss, with time or temperature, of a sample decomposing thermally under controlled conditions. It is often necessary to prepare, from this record, a curve of the rate of weight-loss as a function of time or temperature, by the somewhat tedious and relatively inaccurate process of graphical differentiation.

In order to assist our investigations on the thermal decomposition process of coal and related compounds, two types of thermogravimetric balances were devised to give automatically precise and continuous records of the differential weight-loss, together with

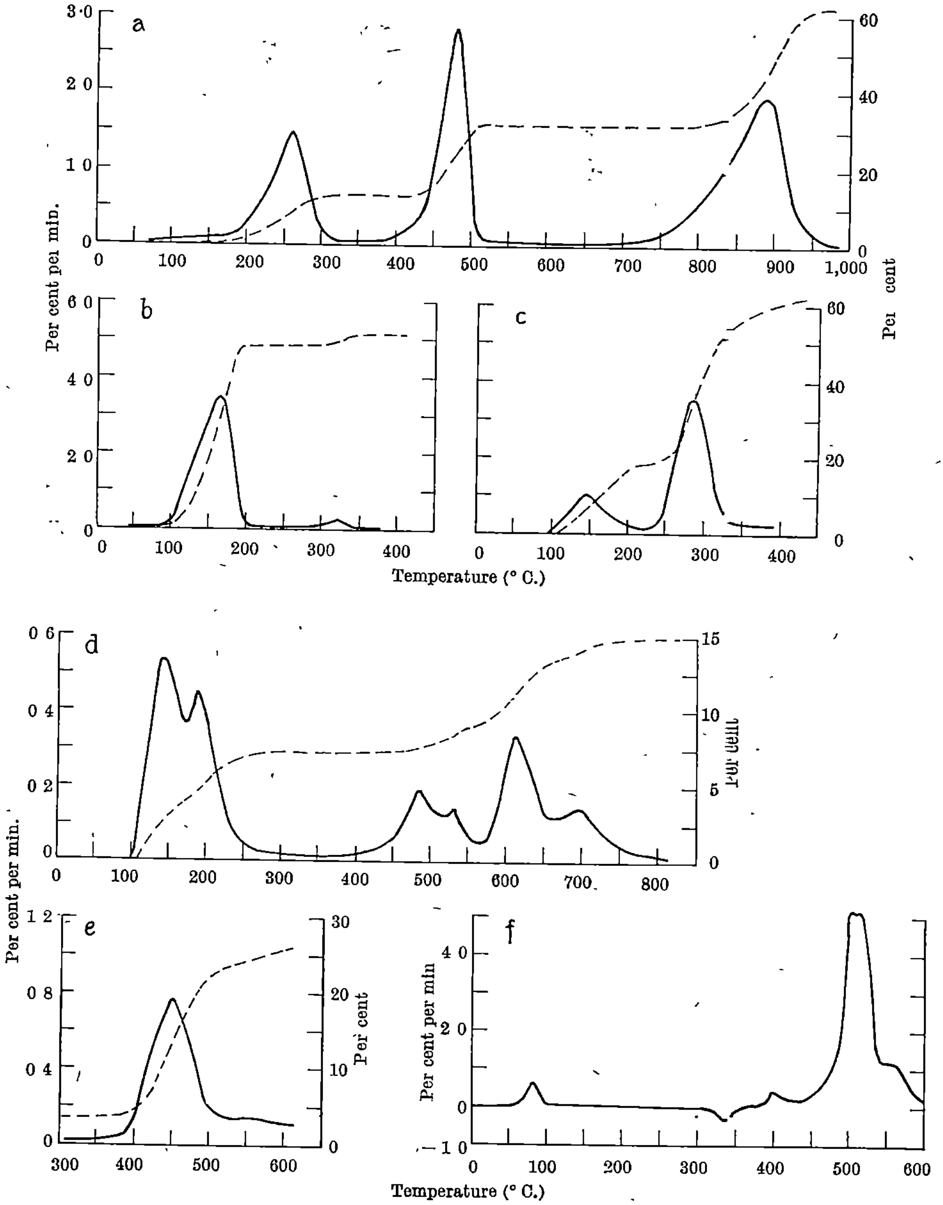

Fig. 1. Examples of differential thermogravimetric curves obtained with prototype balance. ———, Differential thermogravimetric curve; – – – –, cumulative weight-loss curve. (*a*) Calcium oxalate, monohydrate; heating-rate, 6 deg. C./min. (*b*) Dibasic sodium phosphate heptahydrate; heating-rate, 3 deg./min. (*c*) Starch, heating-rate, 3 deg./min. (*d*) Shale from Victoria Tunnel coal seam, N.S.W.; heating-rate, 6 deg./min. (*e*) Coal sample, Victoria Tunnel seam; heating-rate, 3 deg./min. (*f*) Coal sample, Victoria Tunnel seam; heated in air at 3 deg./min.

the usual cumulative weight-loss. These balances, briefly described herewith, differ in principle from the differential thermogravimetric balances already described by De Keyser[1], and Erdey *et al.*[2]. So far as I am aware, these are the only apparatuses of this kind which have been reported.

In the present apparatus, the balance system is maintained in a state of continuous equilibrium by means of a counterbalancing force, applied at the necessary rate, proportionally controlled by an electromotive force equivalent to the rate of loss in weight. It is virtually a null-point balancing system with regard to the rate of weight-loss. The methods of electro-mechanical linkage, however, differ in the two types.

In one design of balance, which has a torsion wire in its construction, the restoring couple necessary to maintain the beam at a certain point of balance was achieved by a special type of servo-motor rotating the torsion head. In the other type, an analytical balance was adapted in such a way that the sample was counterbalanced by the suspended electrode of a silver coulometer, arranged so as to minimize surface-tension effects: as the sample changed in weight, balance was maintained by a corresponding change in weight of the silver electrode due to a control current passing through the cell. The necessary voltage and current controls, in both these types of balances, were effected by a photocell movement detector, and magnetic amplifier with an output rectifier. An 'ohmic drop' in the output circuit enabled a proportion of the controlling voltage or current to be recorded as a measure of the differential weight-change. Integration of this function by electromechanical means also enabled an accurate record of the cumulative weight-change to be made simultaneously on the multi-point potentiometric recorder.

The prototype torsion-wire balance, which is now in continual routine service, can record total weight-changes of up to 0·5 gm. at a maximum rate of 30 mgm. a minute ; the cumulative weight-change may be read to an accuracy within 1 per cent, and the differential weight-change may be determined to within 0·2 mgm. per minute. The differential pyrolysis curves obtained by this instrument are of value in the characterization of coal by rank, and for studies of their mechanism of thermal decomposition. These curves are also particularly useful for providing information of a complementary nature which may be correlated with other thermal properties of coal measured by such techniques as differential thermal analysis and plastometry.

Although originally designed for coal research, the apparatus should also find useful application in other fields of work such as inorganic and organic analyses, mineralogy, adsorption studies and the analysis of the particle-size distribution of powders by sedimentation. Some examples of the decomposition of certain inorganic and organic substances under linear heating-rates are illustrated in Fig. 1. The apparatus and its application to studies of the thermal behaviour of coal and related compounds will be described in detail elsewhere.

The work described here was carried out as part of the programme of the Coal Research Section of the Commonwealth Scientific and Industrial Research Organization, Australia.

Evidence for Substructure in Single Crystals of Potassium Chloride

MEASUREMENTS of the optical scattering and polarization of the ionic current in single crystals of potassium chloride have recently been made.

The variation of the intensity of the scattered light with the angle of scatter was measured for monochromatic ultra-violet ($\lambda = 3650$ A.). The crystal was suspended in benzene, which has a refractive index very close to that of potassium chloride ($n = 1{\cdot}55$). The scattered light intensity was measured with a sensitive photo-electric apparatus using a lock-in detector based on the 100 c./s. modulation of the mains-operated mercury arc light source. The curves in Figs. 1 and 2 show the difference of the intensities of the light scattered from the crystal immersed in the liquid and from the liquid alone. Curve I (Fig. 1) shows the angular distribution of the light scattered from a single crystal of potassium chloride cooled slowly after growth from the melt, and curve II shows the results for the same crystal after quenching in air from 700° C. to room temperature.

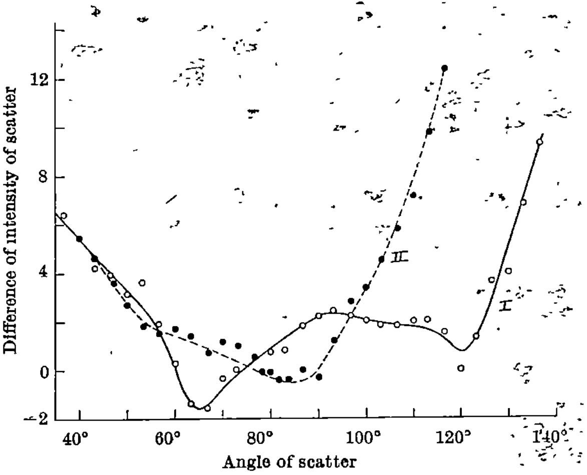

Fig. 1. O—O—, Untreated ; ●—●—, quenched

The deviations from a simple Rayleigh scattering curve indicate the presence of internal scattering structures of fairly uniform dimensions of the order of the wave-length of the light. The results are similar to those obtained by Humphrey-Owen[1] for the variation of the scattering at 90° with wave-length in single crystals of sodium chloride and suggest a comparison with Mie's scattering theory. This applies to isolated spherical particles (radius r) of refractive index differing from that of the surrounding medium. The theory predicts a scattering curve having one or more minima the angular positions of which depend on the parameter $\alpha = 2\pi r/\lambda$. Typical curves for $n = 1{\cdot}5$ plotted from the tables compiled by the National Bureau of Standards[2] are shown in Fig. 2. The position of the minimum in the experimental scattering curve I of Fig. 1 for the normal crystal corresponds to a value α of about 1·1 and hence to a diameter of about 1300 A. for the equivalent scattering spheres. Curve II shows that the dimensions of the scatterers are reduced by quenching ; the position of the minimum and the ratio of the light intensities scattered

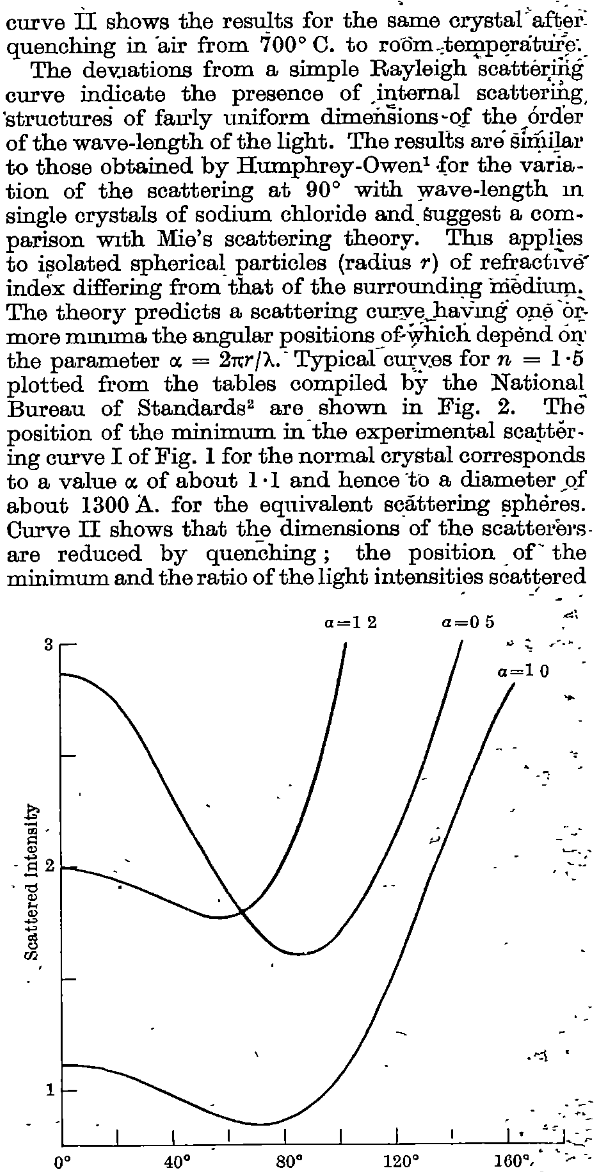

Fig 2

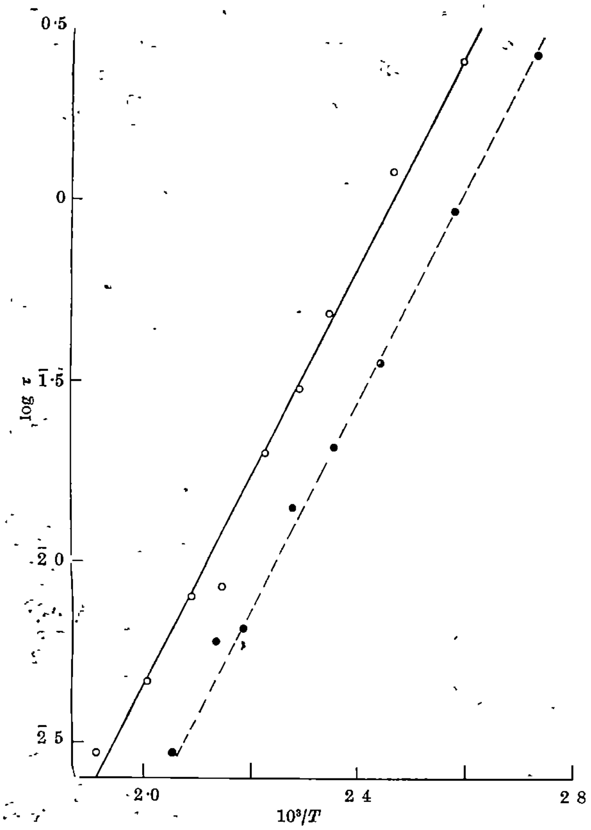

Fig 3. ○—○—, Untreated; ●—●—, quenched

in the forward and backward directions indicate that α lies between 0·5 and 0·8 and thus 2 r between 600 and 900 A.

The electrical measurements were carried out in connexion with investigations on the ionic conduction of single crystals of a number of alkali halides over the temperature-range 20°–300° C. The d.c. method used in these investigations, essentially as described by Cunnell and Schneider[3], allows ionic polarization effects to be observed in detail. Such effects were found in all alkali halides investigated and were established to be intrinsic and not electrode or surface effects. In its simplest form, polarization is observed as a decay of the ionic current, following the application of a constant potential ('step'), from a high initial value to a lower steady value. The rate of decay described quantitatively by a polarization time τ, the time of decay to a current-value half-way between initial and final currents, depends on the temperature of the applied potential and the thermal and mechanical history of the specimen. The temperature dependence follows $\tau = \tau_0 \exp(-u/kT)$ with an activation energy u near the migration energy of positive ion vacancies.

Measurements with specimens cleaved from the same single crystal of potassium chloride as the sample used in the scattering experiments have shown that the polarization time is markedly decreased by quenching, while over a wide temperature-range both the initial and final values of the ionic conductivity are unaffected. Fig. 3 is a plot of log τ *vs* $1/T$ for a potassium chloride crystal before and after quenching in air from 700° C.

Polarization may be explained as a blocking of the ionic current by internal boundaries. According to Jaffe's theory[5] of the rate of build-up of space charge involved in such blocking phenomena, the polarization time should be proportional to the square of the distance between the boundaries. The ratio of the observed polarization times in the untreated and quenched crystals is 2·24, which would indicate that the average distance between the blocking boundaries is decreased by quenching by a factor of 1·5. On the assumption that Jaffe's theory is applicable in detail, together with the accepted value for the diffusion coefficient of positive ion vacancies, the actual value of the distance between blocking boundaries is estimated to be of the order of 2000 A.

The fact that both the distance between internal boundaries which determines the polarization of the ionic current, and the dimensions of the structure giving optical scattering in potassium chloride, are reduced in about the same ratio by quenching, suggests that the same internal structure is responsible for both effects.

The Minimum of Melting Point in Homologous Series

Last year, in a letter in *Nature*[1], Foster and Hammick pointed out the similarities of the curves of the melting points against the length of the hydrocarbon chain, with a minimum in C_5, for both the alkylanilines and alkylnaphthols. They seem not to be aware of similar comments made previously, notably by Lee[2]. Lee suggests that this characteristic results from a helicoidal structure of long hydrocarbon chains which, as in the tension theory of Baeyer on carbon rings, would have a periodicity of 5 carbon atoms.

Against this hypothesis there are the following objections: (*a*) The anomalies for the C_5 term ought to be observed for other properties also, and to be recurrent for the terms in C_{10}, C_{15} and so on, which is not the case. (*b*) In my book "Les Constantes Physiques des Composés Organiques Cristallisés" (Masson, Paris, 1953), pp. 270–304, are quoted some hundreds of series, with the necessary data, and it is shown that the minimum of melting point may equally well be at any term from C_1 to C_{12}. (*c*) Radiograms of long-chain organic compounds show that, in the crystalline state, their molecules may be considered as long rods without any helicoidal structure.

My interpretation of these facts is as follows: in long-chain derivatives the functional radical is of secondary importance only, and has a rather small influence on the melting point; all these series have parallel melting point curves, which converge to a common limit of about 120° C.; only the hydroxyl and amino derivatives have much higher melting points, resulting from hydrogen links, but converge to the same temperature limit. For the first term of a homologous series, on the contrary, the melting point is essentially fixed by composition, functional structure and stereochemical configuration; when a hydrogen atom is replaced by a short hydrocarbon chain, the symmetry of the molecule diminishes and the melting point falls progressively until the falling curve cuts the rising curve of the higher terms of the series. Therefore the position of the minimum is determined by the weight of the functional radical; the heavier the radical the higher in the series is the minimum, as with the α-brom-β-naphthylamides and the alkyl-iodides of mercury, where it is as far as C_{12}.

Evaporation from an Electric Arc in Vacuum

FOR some time, workers producing thin films *in vacuo* have questioned whether an electric arc could be used for evaporating metal films. The method is a possible solution to the problem of evaporating metals of low vapour pressure such as platinum, which cannot be easily evaporated from the commonly used metal filaments because they dissolve the support. Further, if both electrodes are of the metal to be deposited, the film will not be contaminated by other metals as occurs when a refractory metal heater is used.

It is therefore of interest to read the recent claim by Hiesinger[1] that metals can be evaporated "... in an arrangement whereby an electric spark is generated between electrodes which consist of the material which is to be deposited in a high vacuum", and, further, "The method can be used with advantage in the form where the ions produced by the electric spark are accelerated by an electric field, so that the energy of atomic impact on the substrate is increased beyond the normally available thermal energy".

Since this was published, Vodar *et al.*[2] have described an apparatus in which the arc was operated intermittently by vibrating the electrodes, using a relay coil. These workers found that the metal atoms were emitted from the cathode (although this was at the lower temperature) and were mainly negatively charged. When the receiver was a conductor and made positive with respect to the cathode "almost the whole of the deposited metal was concentrated on the support under tension".

Recently, I discovered an early patent by Edison[3] on a "Process of Duplicating Phonograms" from which the following is quoted: "The phonogram so impressed with the phonographic record is placed in a high vacuum, in which an electric arc, continuous or discontinuous, is produced between electrodes of metal or in which metal vapour is otherwise produced. The electric arc produces a vapour of the metal of which the electrodes are composed, which vapour is deposited on the indented surface of the phonogram".

It is doubtful if Edison's electric arc was operated at the pressure now generally understood as 'high vacuum', that is, 0·1 micron mercury or less (Vodar *et al.* operated their arc at 0·01 micron mercury), because apart from other factors the pumping apparatus was not sufficiently developed.

It would be useful to know the type of apparatus Edison used, because it is often difficult to operate continuously an arc in high vacuum; after the arc is struck the supply of metallic vapour may be insufficient for ionization to maintain the arc. Thus the use of an intermittent arc by Vodar *et al.* whereby the arc is periodically re-struck is a novel solution.

The same difficulty is not experienced when an arc is operated at higher pressures (> 10 microns mercury) because a supply of positive ions for the maintenance of the arc can be obtained from the gas. The discharge then occurs in mixed vapour and gas, and both anode and cathode can reach sufficient temperature to evaporate rapidly. Rossin[4] states that in the arc melting of metals the vapour emitted from the molten anode is the conductor and that it is confined in the arc by the gas molecules at a pressure of 10 mm. mercury; but at 10μ mercury the arc becomes unstable due to free evaporation of the metal. Evaporation may take place from a cathode during cathodic sputtering at high current densities in a glow discharge. Thus both zinc and cadmium cathodes will evaporate rapidly if their temperature is allowed to rise during cathodic sputtering. The metal vapour is ionized and the glow may change to an arc if the current is not limited.

It appears that there are at least three mechanisms by which vapour can be produced in electric arcs, namely: (1) sputtering from the cathode under ion bombardment; (2) thermal evaporation of the cathode; (3) thermal evaporation of the anode.

The recent work of Germer and Boyle[5] on short-field emission arcs indicates that thermal evaporation from the cathode electrode may be due to the melting of surface prominences by the field emission currents flowing through them. Thus the evaporation of the cathode electrode noted by Vodar *et al.* may not have been due to ion bombardment as they assumed. A further study of the electric arc *in vacuo* would be of value in view of its potential use as a vapour source for film deposition.

A Simple Method of producing Visible Patterns of Tape-recorded Sounds

WHILE visiting our laboratory, R.-G. Busnel of France directed our attention to a brief note by Pasquinelly[1] on making visible the magnetically oriented areas on tape recordings by immersing the tape in a viscous liquid suspension of ferromagnetic powder and draining off the excess. We have found a modification of this method useful for studying sounds of animals recorded on magnetic tape. Immersion proved unsuitable, because it did not produce clear patterns, and the recorded tapes were difficult to clean afterward.

Dry carbonyl iron powder (General Aniline and Film Corp., Types *E* and *SF*), however, produces good images of tape-recorded sounds, and we propose the name 'ferrograms' for these visible patterns. The recorded surface of the tape is drawn through a thin layer of the powder spread on smooth paper and the excess powder blown or snapped off. The powder is held on the tape at the regions of uniform magnetic orientation, forming images of the recorded sounds.

The spacing of bands on the tape is related to the frequency and temporal distribution of the sound and sound pulses and the density of deposit to the intensity. We have used this successfully with four brands of recording tape, although the results are better with some than with others.

These images are either photographed or removed from the tape by applying to it the sticky surface of a strip of adhesive transparent tape ('Texcel' or 'Scotch'). The adhesive tape is fastened on white paper or transparent cellulose film for permanent storage and detailed study. When mounted on a transparent material, the ferrograms can be made directly into lantern slides. The adhesive tape should be relatively new and unheated, otherwise damage to the recording tape may result, and it is well to press the adhesive surface as gently as possible on to the recording tape. After the pattern has been copied or removed, the recording tape is wiped free of powder and seems to be unaffected.

Fig. 1 shows some ferrograms thus produced. The use of this method to study the 'song', a series of short noise pulses, of a grasshopper, *Neoconocephalus ensiger*, is illustrated. Knowing the tape speed, it is easy to measure directly the duration of the chirps in this 'song', even though these are only 0·02–0·1 sec. in length. With magnification, the number, duration and spacing of the pulses in the individual chirps and other details can be studied. Comparison of the ferrograms with the oscillograms produced by the usual methods shows that they give good representations of the duration of the chirps and pulses composing the chirps and their relative intensities. The remaining ferrograms in Fig. 1 illustrate patterns produced by other sounds. The sound of the tuning fork, in contrast with the others, is relatively simple, and the pattern can be used for determining the frequency as well.

The recording-level must be relatively high for development of the patterns. There is a threshold-level below which no adhesion of the powder occurs. The method seems particularly suitable for noise pulses, such as the stridulatory sounds of many nsects, where the instantaneous intensity of the ndividual pulse may be very high, although the average intensity is not, and where the chief interest ies not in analysis of frequency and intensity but n the distribution and duration of the sound pulses.

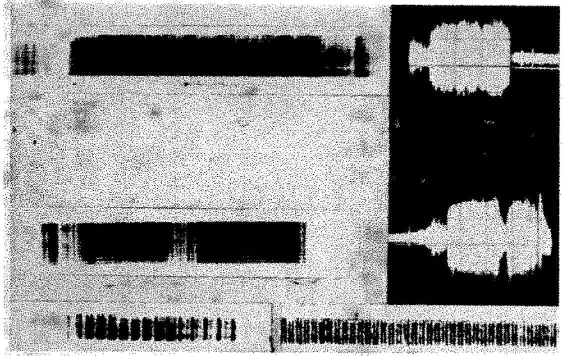

Fig. 1. Top and middle rows, ferrograms (left) and corresponding oscillograms (right) of chirps of *Neoconocephalus ensiger* at 18° C., recorded at 15 in./sec. tape speed; the duration of the chirps is about 1/10 sec. The upper record is the usual type for this species; the middle one is unusual in having a break in the main sound sequence. Bottom left, human voice saying syllable '*Ba*' recorded at 7½ in./sec. Bottom right, tuning fork (256 c./s.), recorded at 7½ in./sec. (All × 1½)

This method for the production of visible patterns of sounds is simple, direct, and uses no expensive equipment. Studies of the temporal characteristics, at least, of sounds can thus be made easily and cheaply by anyone who has a tape recorder.

This work was supported in part by Research Grant No. *E*-802 from the National Microbiological Institute of the National Institutes of Health, U.S. Public Health Service. We wish to thank Dr. Ackerman of this University and the General Aniline and Film Corporation for supplying the carbonyl iron powder, and Dr. Smyth of this Department for assistance in making the oscillograms.

Combinatory Notation

CURRENT notation used in combinatory formulæ is by no means uniform, sometimes clumsy, as in $\binom{n}{r}$, and sometimes misleading in a factual sense as is ${}^nC_r$ or ${}_nC_r = {}^nP_{r.n-r}$. I have elsewhere pointed out advantages of using $n^{[r]} = n(n+1)\ .\ .\ .\ (n+r-1)$ by analogy with $n^{(r)} = n(n-1)\ .\ .\ .\ (n-r+1)$ and $n_{[r]} = n^{[r]} \div r\,!$ in conformity with Aitken's usage $n_{(r)} = n^{(r)} \div r\,!$. In this notation $r_{[d]} = F_{r.d}$ specifies the entire family of Pythagorean figurates defined by $F_{1.d} = 1 = F_{r.o}$ and $F_{r.d} = F_{(r-1).d} + F_{r.(d-1)}$, just as $r_{(d)}$ specifies the term of the rth column and dth row of the derivative Pascal triangle. In combinatory terms, we may write for the number of different r-fold samples from a set of n distinguishable objects:

	Without restriction on repetition	With no repetition
Permutations	n_r	$n_{(r)}$
Combinations	$n_{[r]}$	$n_{(r)}$
Sum of combinations (from $r = 0$ to $r = n$)	$(n+1)_{[n]} = \dfrac{(2n)!}{(n!)^2}$	2^n

The multinomial theorem is valid for $\rho = r$, (r) or $[r]$ in the form $(A + B + C\ .\ .\ .\ )_\rho$, and the combinatory interpretation of the general term becomes more explicit if we write $n_r = n^r \div r\,!$ by analogy with $n_{(r)}$ and $n_{[r]}$ defined as above. We may then write the general term of the following expansions as on the right below:

$$
\begin{array}{ll}
(A + B + C\ .\ .\ .)^r & r\,!\,A_u \,.\, B_v \,.\, C_w\ .\ .\ . \\
(A + B + C\ .\ .\ .)^{(r)} & r\,!\,A_{(u)} \,.\, B_{(v)} \,.\, C_{(w)}\ .\ .\ . \\
(A + B + C\ .\ .\ .)_{[r]} & A_{[u]} \,.\, B_{[v]} \,.\, C_{[w]}\ .\ .\ . \\
(A + B + C\ .\ .\ .)_{(r)} & A_{(u)} \,.\, B_{(v)} \,.\, C_{(w)}\ .\ .\ .
\end{array}
$$

By specifying the number of r-fold samples containing u of sub-set A, v of sub-set B, w of sub-set C, etc., of an n-fold set ($n = A + B + C\ .\ .\ .$), the following table then subsumes in an economical notation all the more familiar formulæ of linear combination and arrangements, including the two forms of what MacMahon calls the "Master Theorem".

	With no restriction on repetition	With no repetition
Permutations	$r\,!\,A_u.B_v.C_w\ .\ .\ .$	$r\,!\,A_{(u)}B_{(v)}C_{(w)}$
Combinations	$A_{[u]}B_{[v]}C_{[w]}\ .\ .\ .$	$A_{(u)}B_{(v)}C_{(w)}$

Selection for Fibre Number in Merino Sheep

CARTER[1] has reviewed work on the hair follicle group in sheep. This review emphasizes breed differences in the ratio of secondary to primary follicles, but does not mention any previous work on selection within a breed. Some preliminary results of a selection experiment are therefore presented, in which changes in both primary and secondary follicle counts per unit skin area have been demonstrated.

One section of a flock of medium-wool Australian merinos at the National Field Station, Cunnamulla, Queensland, consists of pairs of families, in which selection is for a high or low value of a single character. In one pair the character under selection is fibre number per unit area of taut skin (N), measured by the technique described by Turner *et al.*[2], which does not differentiate fibres from primary and secondary follicles. The groups were founded with animals drawn from one flock, chosen as being of average body-size, but ewes for the high group (HN) being required to have a fibre number above the mean plus one standard deviation, and those for the low group (LN), a fibre number below the mean minus one standard deviation. The foundation rams were chosen from the same flock as the ewes, the most extreme available being selected. Recruitment is from within each family, selection being made at 15–16 months of age.

Although follicle counts have not been required in selection, a skin sample has been taken from the centre of each clipped area immediately after removal of the wool sample. Counts per mm.^{2} of primary (P) and secondary (S) follicles have been made and the ratio S/P (R) calculated, using the techniques described by Carter and Dowling[3].

The mean fibre number for unselected progeny of the HN group each year has been consistently above the mean for those of the LN group. Of great interest is the fact that differences in both P and S contribute to the differences in N, the HN progeny having higher mean counts than the LN progeny for both types of follicle. Over the three sets of progeny now available, the weighted mean differences are $0{\cdot}50 \pm 0{\cdot}13$ for P and $19{\cdot}1 \pm 3{\cdot}3$ for S, both being significant at the 0·1 per cent level. The weighted mean difference in R is $3{\cdot}2 \pm 1{\cdot}1$ (significant at the 1 per cent level), the HN progeny again having a higher value than the LN.

The classic picture of the follicle population in the sheep is one of a series of groups, each containing a trio of primary follicles, with associated secondaries. If it is assumed that the number of primaries in a group remains unchanged, then changes in P indicate changes in the number of groups, while changes in R indicate changes in group-size. The two sources of change may possibly differ in their effect on the amount of wool produced per unit area of skin, and the relative importance of each is not yet known. Further investigations on this point are in progress.

Observed changes in S and P can be separated into those arising from the purely mechanical effect of changes in surface area, in which the total follicle number on the sheep is not altered, and those arising from environmental and genetic influences on the follicles themselves, in which the follicle number is altered. The purely mechanical effects have been eliminated in the present data by adjusting counts for difference in body-weight, taking surface area as approximately proportional to (body-weight)$^{2/3}$. It has sometimes been suggested that R should be used as an indicator of follicle or fibre population, because it is independent of mechanical changes due to variation in surface area. Since the present results have shown that P, S and R can all be influenced by selection, increases in R will not necessarily indicate increases in ($S + P$), as can be shown by the following discussion.

If we denote changes in P by δP, in S by δS and in R by δR, then we have :

$$R + \delta R = \frac{S + \delta S}{P + \delta P}$$

$$= R\left(1 + \frac{\delta S}{S} - \frac{\delta P}{P} - \frac{\delta S.\delta P}{S.P} + \frac{(\delta P)^2}{P^2} + \ldots\right)$$

Changes in R will thus depend on the relative size of $\frac{\delta S}{S}$ and $\frac{\delta P}{P}$, and the following will hold :

(1) If $\delta P = 0$, R will change with δS, and will be an indicator of ($P + S$).

(2) If $\left|\frac{\delta S}{S}\right| = \left|\frac{\delta P}{P}\right|$, both being of the same sign, R will be constant, irrespective of changes in ($P + S$). Proportional changes in S and P could arise from the mechanical effect of changes in body-size, in which case R would be of value in comparing follicle populations. Such changes could also arise, however, if the number of follicle groups increased but R remained the same ; in this case R could be misleading if used alone in comparing follicle populations.

(3) If $\left|\frac{\delta S}{S}\right| < \left|\frac{\delta P}{P}\right|$, both being of the same sign, R will *decrease* when ($P + S$) is *increasing* (that is, δS positive) but *increase* when ($P + S$) is *decreasing* (that is, δS negative).

Thus if follicle counts are used in comparing sheep, both P and R are necessary to obtain an estimate of the follicle population, together with body-weight, to enable an adjustment to be made for variation in surface area.

I thank various units of the Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, for their assistance. Counts were made at the Sheep Biology Laboratory, Prospect, while the sheep were maintained and sampled by the staff of the National Field Station.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT CHEMIST (Fuel Technologist) (preferably with a degree in fuel technology or equivalent qualification, and previous industrial experience) in the Divisional Chemical Laboratory, Skelton Grange Power Station, Leeds, to be responsible for directing the work of the Fuel Section of the laboratory and to investigate general problems of fuel technology—The Divisional Secretary (Establishments), Central Electricity House, St. Mary's Road, Leeds 7 (August 18).

ASSISTANT LECTURER (with a good honours degree in physics or physical chemistry, and prepared to undertake research work on fibres) IN PAPER TECHNOLOGY in the Department of Textile Chemistry—The Registrar, College of Technology, Manchester 1 (August 20).

DRAUGHTSMAN IN THE DEPARTMENT OF ARCHÆOLOGY, to prepare for publication, scale drawings of objects, plans, diagrams, etc.—The Secretary, National Museum of Wales, Cardiff (August 20).

RESEARCH ASSISTANT (with at least an ordinary degree in physics or equivalent qualification) IN ROCK MAGNETISM in the Geophysics Section of the Department of Geology, for work on problems in palæomagnetism—The Registrar, The University, Birmingham (August 20).

ASSISTANT PHYSICIST, Basic grade (with a good honours degree in physics, and preferably experience in electronics and nuclear physics techniques) in the Physics Department of the Sheffield National Centre for Radiotherapy—The Secretary, "Broom Cross", Tree Root Walk, Sheffield 10 (August 24).

CARTOGRAPHER IN THE DEPARTMENT OF GEOGRAPHY—The Head of the Department of Geography, The University, Hull (August 24).

COMPUTER IN THE DEPARTMENT OF ECONOMICS—The Registrar, University College, Singleton Park, Swansea (August 25).

LECTURER or ASSISTANT (with a good honours degree in botany or agricultural botany) IN AGRICULTURAL BOTANY—The Secretary of the University Court, The University, Glasgow (August 25).

SENIOR SCIENTIFIC OFFICER (with a university degree in science, preferably with honours, with physics as the major subject, together with considerable experience of applied research in the field of physics), to be responsible for the planning and execution of research and related work in physics—The Director, Institute for Industrial Research and Standards, Glasnevin House, Ballymun Road, Dublin, Ireland (August 25).

ASSISTANT IN ELECTRICAL ENGINEERING—The Secretary of the University Court, The University, Glasgow (August 31).

ASSISTANT (with a degree in horticulture or botany or equivalent experience) IN THE POMOLOGY SECTION, to help with field experiments and in the supervision of recorders—The Secretary, East Malling Research Station, near Maidstone, Kent (August 31).

LECTURER IN THE DEPARTMENT OF METALLURGY—The Registrar, The University, Liverpool (August 31).

SENIOR LECTURER IN THE DEPARTMENT OF VETERINARY HYGIENE AND PREVENTIVE MEDICINE—The Secretary, University of Edinburgh, Royal (Dick) School of Veterinary Studies, Edinburgh (August 31).

SENIOR LECTURER (with special qualifications in taxonomy, and preferably acquainted with African flora) IN BOTANY, at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

ASSISTANT LECTURER or LECTURER IN CLINICAL PSYCHOLOGY—The Registrar, The University, Leeds 2 (September 1).

CHEMISTS (with a first- or second-class honours degree or equivalent qualifications) at the Ministry of Supply Tropical Testing Establishment, Port Harcourt, Nigeria, for work on general problems associated with the scientific study of the behaviour of a wide variety of materials (plastics, rubber, metals, fibres, etc.) in tropical environments—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.51/6A (September 1).

SENIOR AGRICULTURAL ECONOMIST (with a good degree in economics or agriculture with economics, together with experience in farm management and advisory work) in the Department of Agricultural Economics—The Registrar, King's College, Newcastle-upon-Tyne (September 7).

ASSISTANT LECTURER (preferably with special interests and qualifications in geomorphology and biogeography) IN THE DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Liverpool (September 8).

LECTURER IN ANIMAL PRODUCTION, and a LECTURER IN CROP AND GRASSLAND PRODUCTION—The Registrar, Wye College, Ashford, Kent (September 15).

LECTURER IN THE DEPARTMENT OF PATHOLOGY—The Secretary, The University, Edinburgh (September 15).

ERNEST CANNING RESEARCH SCHOLAR (with a good honours degree in metallurgy, chemistry or physics, and industrial or research experience) for fundamental research in metal finishing—The Registrar, The University, Nottingham (September 29).

LECTURER (with a degree in industrial chemistry or chemical engineering, preferably with honours, or an equivalent degree, and industrial experience in the field of industrial chemistry and/or chemical engineering) IN INDUSTRIAL CHEMISTRY at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

DIRECTOR OF RESEARCH—The Chairman of Council, The British Electrical and Allied Industries Research Association, Thorncroft Manor, Dorking Road, Leatherhead, Surrey, marking envelope "Director—Confidential" (October 1).

KEEPER OF THE DEPARTMENT OF ANTIQUITIES in the Ashmolean Museum—The Registrar, University Registry, Oxford (October 1).

LECTURER IN METEOROLOGY—The Secretary of Faculties, University Registry, Oxford (October 1).

SENIOR LECTURER IN PSYCHOLOGY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 1).

DEPUTY DIRECTOR (with a second-class honours degree in agriculture or sciences pertaining to agriculture, plus a high standard of basic education) OF THE WEST AFRICAN INSTITUTE FOR OIL PALM RESEARCH, Nigeria, to deal with all the Institute's business under the general instructions of the Director; to co-ordinate and organize the work of the research divisions; and to assist in the drawing up and directing of the Institute's research programme—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD/197/199/011.

FIELD OFFICER (Agriculture) (aged 30–40, with sound tropical experience of experimental farm management and a knowledge of preparing and recording experiments) IN THE TANGANYIKA GOVERNMENT AGRICULTURAL DEPARTMENT—The Crown Agents, 4 Millbank, London, S.W.1, quoting M3A/43540/TA.

LABORATORY SUPERINTENDENT (with A.I.S.T. or equivalent, and laboratory experience, preferably in geology or inorganic chemistry) IN THE NIGERIAN FEDERAL GOVERNMENT GEOLOGICAL SURVEY DEPARTMENT—The Crown Agents, 4 Millbank, London, S.W.1, quoting M3/43508/NF.

LECTURER (with an honours degree of a British university, and preferably industrial or teaching experience) to teach primarily Organic Chemistry—The Principal, Stockport College for Further Education, Wellington Road South, Stockport.

SENIOR SCIENTIFIC/SCIENTIFIC OFFICER (with a first- or second-class honours degree in physical or inorganic chemistry, or equivalent qualifications) to undertake basic research involving the study of various physical and chemical properties of solids at very high temperature (Ref. 1220/34); and SCIENTIFIC OFFICERS (with a first- or second-class honours degree in physics, mathematics or engineering, or equivalent qualifications) to carry out research and development work in the field of applied mechanics (Ref. 1221/34)—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting appropriate Ref. No.

SPECIALIST ASSISTANT (with a degree in science or agriculture or NDA) IN THE AGRICULTURAL DEPARTMENT, Government of Northern Nigeria, to form part of a Soil Survey Team—The Crown Agents, 4 Millbank, London, S.W.1, quoting M3A/35300/NF.

TECHNICAL OFFICER (with a degree in agriculture or equivalent qualifications) for cereal multiplication—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

TECHNICIAN IN THE DEPARTMENT OF BOTANY, for duties primarily in connexion with the teaching and research work of the Department in Mycology and Plant Pathology—The Professor of Botany, The University, Southampton.

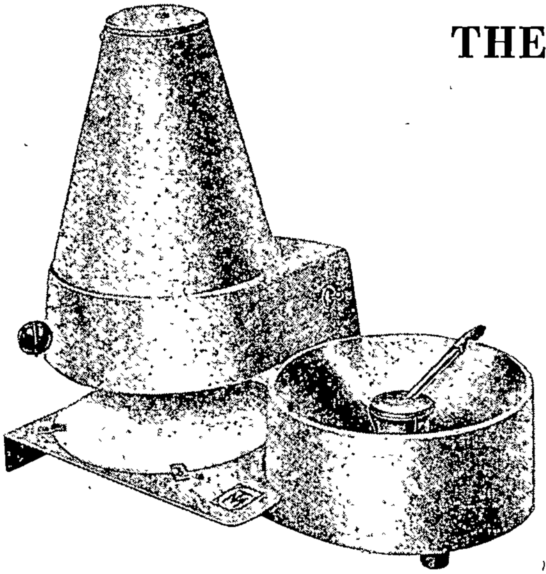
THE INFRA-RED ASHING MICRO-INCINERATOR

complete with "suction lid"



This is an ingenious device for ashing biological matter in a nickel crucible, under a concentrated beam of infra-red rays.

Normal ashing takes about 10 minutes or less.

The crucible is at the centre of a gold-plated parabolic mirror and receives the full beam of 250 watts. A neat cap with tube fits over the crucible and connects to a water pump, if objectionable smells are likely.

A BALANCED EDUCATIONAL SYSTEM

THE debate on technical education in the House of Commons on June 21 drew from the Minister of Education and the Lord Privy Seal further details of the Government's plans for the development of technical and technological education in Britain (see *Nature*, 177, 1204 ; 1956). Sir David Eccles named eight colleges which he proposed to designate as colleges of advanced technology and indicated the probable geographical location of two more. Mr. R. A. Butler gave some figures for the proposed Government expenditure on buildings for university departments of technology and for higher technological education without, however, indicating clearly how far, or not, this overlaps with the building programme to which Sir David Eccles referred and which appears to cover the proposed colleges of advanced technology, to seven of which, as well as the Imperial College of Science and Technology, London, the Royal Technical College, Glasgow, and the Manchester College of Technology Mr. Butler specifically referred. The distinction between these three and the eight colleges of advanced technology which Sir David is proposing to designate is still not clear, except that, unlike the former, the latter colleges will confer diplomas in technology and not degrees.

The proposed Hives award was severely criticized in the debate. Sir David's defence of the decision to introduce this award was unconvincing and did not meet the reasoned argument in the debate that the institutions in which technological education is to be given should be in close relation with the universities and, if independent, should be capable of giving degrees in technology carrying the status of a degree given by a university department of technology. The objection to the diploma, however, would largely be avoided if more attention had been paid to the major professional institutions. The associateship and fellowship of these institutions are already regarded in industry and technology generally as having a status as high as that of a university degree. It is at least arguable that the new colleges of advanced technology would achieve the desired standing much more quickly if they relied either on such professional awards or on degrees conferred by an associated university rather than on a new award which, quite apart from the obvious prejudices it encounters at the start, must require many years to establish its standing.

Too much can be made of this point, however, for the real value of the award, by whatever name it is called, will depend on the value which industry places on the men who earn it. If they can hold their own with those now coming from the technological departments of the universities, from the Imperial College of Science and Technology, the Manchester College of Technology and the Royal Technical College, Glasgow, there will be no question of inferior status ; but, as Mr. M. Stewart rightly said in opening the debate, it is no use calling a college a 'college of advanced technology' if it cannot do the work. The Minister, however, probably realizes already some of the difficulties, for he made perfectly clear in the debate that the conditions which a college must fulfil to qualify for designation as a college of advanced technology will be stringent, as is to be seen from the circular issued simultaneously (see *Nature*, June 30, p. 1204).

Manifestly, the Minister carried the House with him in all this. The real question is whether he was carrying concentration sufficiently far. It is, to say the least, doubtful whether Britain has, or can have in the next few years, the resources to establish ten new major technological institutions, considering not merely the problem of staffing them adequately but also of equipping them. Both geographical criteria and the criteria of standard of work might well be applied much more searchingly than Sir David appears to contemplate doing. To do so might, moreover, ease the solution of his other problem—that of autonomy. While Manchester has shown that local authorities can, and do, take a national view, it may well be questioned whether it is reasonable to expect them to do so ; nor with the example of national parks administration before us can optimism be felt that the national interest will always prevail where it clashes with local desires. The complete free trade in students is far more likely to be assured if the colleges are given real autonomy, and without it there is reason for doubting whether they will attract staff of really high calibre. With a severely limited number of colleges of advanced technology, not only should there be more reasonable prospects of staffing them adequately but also there would be less over-riding of local interests. Local authorities would be able to demonstrate in the running of the technical colleges, particularly at the area and regional level, their ability to take wide views of their responsibilities.

The debate, which incidentally brought a further request for something on the lines of a Technological Grants Committee, as an independent body or a sub-committee of the University Grants Committee, showed that both sides of the House of Commons are now well aware of the danger of dissipating the educational resources of Britain, and also appreciate the importance of maintaining high standards and appropriate conditions of service to enable the new technological institutions to achieve their purpose. Moreover, in spite of something of a dichotomy between the colleges of technology and the university departments of technology in both Sir David's speech and in that of the Lord Privy Seal, there is a growing readiness to look at the expansion of technical and technological education as part of the expansion of education as a whole. This was apparent in Sir David Eccles's speech no less than in those from the Opposition benches ; for although Sir David dealt mainly with technical education, he made it clear at the outset, not merely that we must avoid dispersing our resources, particularly of teachers, over too many technical colleges, but also that we must try to keep a balance in the various advances we are trying to make between one part of the education service and another.

Sir David's speech was thus important as giving a clearer picture of the Government's general policy or structure in technical education. Broadly speaking, and leaving aside certain national colleges like the National Foundry College, the Minister said that there are at present three types of technical college, to which the White Paper proposed to add a fourth. First, there are in England and Wales some three hundred local colleges providing part-time or full-time courses up to the level of Ordinary National Certificate. These in the main train the technicians and craftsmen. Next, covering much the same ground but also providing more advanced courses, mostly part-time, come the area colleges, of which there are at present about a hundred and fifty. Many of these, however, are in need of expansion, and provision for this is made in the building programme to which Sir David referred later in his speech. Thirdly, there are the regional colleges, of which in a few years time there may be thirty. While these colleges would cover a good deal of the same ground as the area colleges, with more advanced work in the form of full-time or sandwich courses, some, such as the North Staffordshire Technical College at Stoke-on-Trent and the Treforest Technical College in Glamorgan, would provide advanced courses in single technologies which would be eligible for the 75 per cent grant. At the apex come the colleges to be designated colleges of advanced technology, which will concentrate entirely on advanced work, including postgraduate and research work, and which the Minister hopes to see built up to something like university status. Besides the eight colleges named in his speech, the Minister indicated that it is hoped to designate in the near future a college to meet the needs of the north-east coast, and also, if sufficient support is forthcoming from industry, the Bristol College of Technology, to meet the needs of the south-west.

If the Minister is to maintain his criteria of standards, it may become necessary to reduce this list and to revise it in order to meet the geographical criteria. Sir David was indeed optimistic as to the supply of teachers, which he admitted is the heart of the problem. He said that the figures for March 31, 1955, are really encouraging, showing about 10,000 full-time and 43,700 part-time teachers in technical colleges, an increase of 800 full-time teachers over the figures of the previous year. Of the part-time teachers, more than 11,000 are school-teachers employed part-time in colleges, most of the others, including many men and women of distinction, being employed in industry.

Sir David was also optimistic that industry would be able to help even more in supplying part-time teachers; but it is doubtful whether part-time teachers can make the contribution in advanced work that he expects. They can scarcely help to foster the residential community which the Minister obviously expects from the stress he laid on the provision of residential accommodation; indeed, the Government's reliance on part-time teaching is a weak point in the scheme, which unfortunately received little attention in the debate. Such teaching has its place, perhaps especially in postgraduate courses; but it has its limitations too, and its influence will be best felt when the part-time teacher is in a relatively small minority on the teaching staff. There is a place, too, for industrialists on the governing bodies of technical colleges, and particularly for men of technical knowledge.

It cannot be stressed too much that we cannot get an adequate system of technical or technological education in Britain on the cheap. There appears to be real danger in the Government's proposals that in trying to expand too fast at the top we may not merely lower standards but also carry into the new colleges something of the niggardliness and parsimony that have handicapped the technical colleges in the past and contributed to their difficulties in securing recognition by the public and in recruiting first-class staff. Moreover, Sir David Eccles did not justify his designations by any reference to the estimated relative demands of industry over the coming years for technicians and technologists, or to the probable increase in the number of 18-year olds in Britain from 640,000 in 1955 to 850,000 in 1965, in terms of either aptitude or inclination for technical and scientific careers. If £15 million for the building programmes for 1957–58 and 1958–59 which the Minister has now approved are wisely expended, the new technical colleges at all four levels should be much more efficient and productive places; though it may well be judged that the contribution to the supply of technicians will be larger and that to the supply of technologists smaller than the Minister expects.

The character and status of the teachers may be affected in the same way, though it should be noted that the Minister is already looking into the training of teachers for technical colleges and has asked the chairman of the National Advisory Council on the Training and Supply of Teachers and the chairman of the National Advisory Council on Education for Industry and Commerce to nominate a small joint committee to advise him urgently upon the recruitment and training of such teachers. He also indicated his awareness of the importance of salaries and other conditions of service, such as a more generous staffing ratio which affords opportunities for research and keeping in touch with industry; and, referring to the importance of the regional colleges and the colleges of advanced technology being available for all students, whether or not they lived in the area of the local authority responsible for the college, Sir David said that any restrictions, anywhere, must be seen to be very fully justified.

Sir David expressed confidence that complete agreement would be reached in the talks now in progress with the local authorities on this question. Even if his confidence is not fully justified, such agreement could well be helped by a much more vigorous Government campaign to persuade parents as to the opportunities and national importance of careers in science and technology. Unless that is undertaken with much more vigour and imagination han has yet been apparent, it is doubtful whether he impending bulge of school-leavers will fill the new places in the science and technological departments of the universities, the colleges of technology or the technical colleges. Sir David himself stressed the importance of first-class public relations in a voluntary system of further education; but he was thinking rather of co-operation with industry and of securing the close personal interest of industrial management both in the technical college and in the schools from which its students are drawn. Mr. S. C. George rightly stressed the need for greater efforts to attract the abler boys and girls into such careers, and Mr. R. A. Butler was ill-advised to gnore Mr. George's request for an assurance that a virile and imaginative campaign would be waged within the schools and among parents to that end.

On the question of teachers, Mr. George, however, was inclined to agree with Sir David Eccles, quoting the opinion of the director of the Royal Technical College, Glasgow, that he does not doubt the ability of Scotland, at any rate, to provide the staff for the new colleges when they are built. Apart from this, there was little support in the debate for the Minister's optimism; though the plea for greater efforts to educate parents as to what is at stake for the industrial future of Britain and so to use their home nfluence to discourage early leaving was repeatedly echoed, notably by Mr. J. C. Jennings. Sir David, in fact, found a large measure of support, particularly n regard to his stress on the need for a balanced policy and for a liberal conception of education which would equip the young men and women entering industry with the adaptability and versatility which they would need.

The importance of this has been emphasized by recent events in the motor-car industry, and there are, of course, measures outside the field of education which the Government could use to encourage adaptability. Broadly, however, the debate showed a large measure of agreement that the magnitude of the Government's programme is about right, having regard to the resources at present available; but that there are serious reservations as to the deployment of resources, more particularly those going nto the colleges of advanced technology. They probably should be fewer and more generously developed as regards amenities, staff and autonomy. Moreover, as regards technical colleges at all levels, here is much which could be done at slight expense o make them more effective and to remove the bleakness which hinders also the development of corporate student life.

Dr. F. Aylward, in a paper on education and ndustry published in *Chemistry and Industry* of May 5, which also stressed the importance of creating in the next few months an informed public opinion, in this connexion referred to the part which the common room and library play in a full education. The technical colleges, however, only too often possess inadequate libraries and reading rooms, comparing unfavourably with a local public library. These are the more important, however, when a large proportion of students are without the privacy for study in their homes and lodgings; and adequate budgets for technical college libraries would do much at small cost to increase the efficiency of the present colleges. Even here, however, the Government cannot wisely ignore the return which a national library system for science and technology, such as the Advisory Council for Scientific Policy has recommended, would bring.

In spite of the further information it contained, the Lord Privy Seal's speech replying on the debate was disappointing. Mr. Butler said that, in 1955–56, actual expenditure on technical education was £7 million, and the University Grants Committee has recently examined the building programme for 1957–59 with particular reference to technology. An increase of 60 per cent in student numbers is anticipated over the next five years, and the Government has already authorized further buildings to be started in 1957, not only for engineering and other technologies, but also for basic science, physics and chemistry, in which technologists require to be well grounded, at an estimated cost of £4·5 million. This figure does not include sums collected by the universities themselves, or the £15 million to be spent on the Imperial College. The London County Council has now given outline approval for the east and west blocks on the island site in South Kensington, and work can now proceed on that part of the plan; but the central part is regarded as somewhat overbuilding the site. The Council is, however, prepared to give permission for certain sites in Princes Gardens to be used for the provision of common rooms and refectories, and this would permit reduction of the density of development on the island site. A revised plan has been prepared which not only gives a lower density of development but also allows the central tower of the Collcutt building to be preserved by the College (see *Nature*, July 21, p. 123); it would be necessary, however, to obtain expert advice on the stability of the tower as a separate unit. It is also proposed to spend about £750,000 at Salford, about £1·5 million at Birmingham on the development of the technical colleges there, and further sums not only at Manchester, where the Corporation is reserving an area of 17½ acres for the development of the Manchester College of Science and Technology, but also at Bradford, Loughborough, the Chelsea Polytechnic and the Northampton Polytechnic in London, and the Cardiff College of Technology. £100,000 has been provided in 1956–57 for developments in Swansea Technical College.

Mr. Butler thus failed to meet the main points of criticism which, for the most part, were very reasonably advanced during the debate; nor did the information he gave indicate precisely the relation of the structure of technical education outlined by the Minister of Education to the university departments of technology, or the distinction between, for example, the Manchester College of Technology and the colleges of advanced technology. What seems beyond question is that the Government should acquire, as a matter of urgency, the factual information as to the nation's requirements in technicians and craftsmen as compared with technologists and scientists, and that meanwhile it should be conducting with energy and imagination the task of public education essential to secure the co-operation of parents and of industrialists. Unless that task is vigorously undertaken and guided by real insight and understanding, it is idle to expect that 'early-leaving' will be reduced, an adequate proportion of the brighter boys and girls attracted into scientific and technical careers or that the understanding and co-operation of industry and local authorities will be fully engaged, either in the management of the technical colleges or in their staffing. If the Government is to rely on voluntary day-time release, much more must be done to bring home to industry its importance; just as the local authorities must be helped to understand the need for regional, if not national, views in running local and regional colleges and parents the need for encouraging young people to stay at school. It is the failure of the Government to deal vigorously and with foresight with these matters, and with those ancillaries like the national library, which contribute so much, directly and indirectly, to the full efficiency of the educational institutions of Britain, that justifies doubts as to whether the urgency and vital importance of a balanced system of education, in which technical and technological education find their appropriate place, are fully appreciated.

ROBERT HOOKE

Robert Hooke

By Margaret 'Espinasse. (Contemporary Science Series.) Pp. ix+192+16 plates. (London: William Heinemann, Ltd., 1956.) 21*s*.

If a scientist who admittedly knew little of poetry were to write a book the chief aim of which was to defend Wordsworth against strictures from Byron and Shelley, the literary reviewers would, rightly, be savage in their attack. The scientists defend their realm less sternly. Of her biography of Hooke, Mrs. Margaret 'Espinasse writes: "My motive in the enterprise is my feeling for Hooke. . . . When I first read his Diary I was enchanted by the personality which seemed to emerge so clearly". This is a valid reason; but many people will find the sustained tendentiousness and lack of scientific depth both tedious and irritating, and those familiar with Hooke's work will wish for more information on it and less defence of his personality.

Hooke, like all the original members of the Royal Society, was a fascinatingly complex thinker and an excellent and original scientist, whose interest in science far outran the study of elasticity which has left us Hooke's Law: he worked in optics, dynamics, pneumatics, physiology, microscopy, horology and chemistry, and was a brilliant inventor and an excellent architect. He is very like Wren in his interests, as the author points out. The originality and inventiveness which Wren poured into architecture Hooke put, with equal success, into the less enduring field of mechanical invention. As Mrs. 'Espinasse rightly remarks, Hooke is particularly interesting as almost the only paid professional scientist of his day. He was lucky that his work aided his science, whereas most of his contemporaries were busy doctors, architects, business men, courtiers, men of affairs, or theologians, who could give only their spare time to science. Hooke, as curator of the Royal Society, was at the centre of a busy, vivid, stimulating intellectual circle, pulsating with ideas, regularly discussing all scientific subjects and advances, both those made at home and those reported from abroad.

Hooke disputed more about priority than the others, Newton excepted; as a professional scientist, it mattered more to him, and he was, besides, a touchy man, quick to feel slighted even by his best friends, and equally quick, usually, to make it up. But Hooke does not need the jealous defence here accorded him; nowadays we do not share the Victorian passion for heroes. We prefer a just appraisal of a man set fairly in his period, and modern scholarship of the past ten years (unfortunately little remarked here) has corrected the earlier Olympian view of Newton. We now know that Newton, like Hooke, was a discursive, experimental, inquisitive scientist, whose works are more systematic than his thought. Hooke, even more true to his age—less the formal mathematician, and more generous in publishing his scientific work (though he was more restrained in declaring his inventions, unfortunately) —eschewed systems. To-day we appreciate non-systematic scientists like Hooke and Huygens more than the eighteenth century could do.

There is much in this book to interest any reader; it is a pity that the author's judgments of Hooke's achievements are often faulty. The air-pump Hooke built is not a forerunner of the steam engine; nor was his nitro-aerial theory of combustion an anticipation of Lavoisier. On the other hand, his theory of light as pulsed waves is more modern, and much more interesting, than is indicated. The descriptions and appraisal of Hooke's mechanical inventions are more just and complete, and are supported by handsomely reproduced illustrations. It is to be hoped that this book will attract interest to the further study of Hooke and his contemporaries, so that we may properly appreciate our predecessors.

MARIE BOAS

ELECTRICITY IN GASES

Ionized Gases

By Dr. A. von Engel. Pp. x+281. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 42*s*. net.

Since the publications of Townsend and Thomson there have been few comprehensive books on this subject which achieve the same standards of clarity in elucidating the basic physical principles. Dr. A. von Engel's book is outstanding in this respect. In a modern work this cannot readily be achieved without considerable sacrifice, and in the present volume, as the author admits, simplifications have been made with consequent loss of detail.

The author states that the book is based on his lectures to undergraduates and, happily, this is true of its style as well as of its content. The result is a book which is delightfully pleasant to read, and makes good the promise in the preface to form an introduction to the subject.

The titles for the various chapters follow the almost inevitable pattern: excitation and ionization;

emission of charges from surfaces; mobility; diffusion; recombination; glow discharges; and arc discharges. It is perhaps appropriate that the author, who has worked for many years in the laboratory made famous by Townsend, should include chapters on conduction in feebly ionized gases and on ionization in an electric field. There is a reasonable degree of uniformity in the standard of treatment of the subject; the one exception to this being the chapter on recombination, which with seventeen pages appears comparatively inadequate. On the other hand, Chapter 3, which deals with individual collision processes, is particularly good and achieves a nice combination of clarity with sufficient detail. In this chapter also, the author's skill in explaining the physical basis of the quantum theory of atomic processes is particularly in evidence. It is not by any means always easy to do this in simple terms, and the explanation that electrons in metals are "so strongly bound that only an insignificant number can contribute to the specific heat of the metal" does not perhaps represent the most important feature of the Fermi levels.

In presenting the latest experimental information, the author has included some results which have since been found to be unreliable. On p. 141, for example, the table of values of electron recombination coefficients has one or two doubtful entries, and in the same category is the statement on p. 143 that molecular positive ions of helium are the principal ions in discharges of this gas at ordinary pressures.

However, these are minor points in an excellent book which will appeal particularly to final-year students and to those embarking on research in this subject. J. SAYERS

BACKGROUND AND PHILOSOPHY OF MODERN PHYSICS

Physics and Microphysics

By Prof. Louis de Broglie. Translated by Dr. Martin Davidson.) Pp. 286+9 plates. (London: Hutchinson's Scientific and Technical Publications, 1955.) 21*s.* net.

THE late Albert Einstein contributes an all too brief foreword to this book, but he aptly sums up the remarkable series of essays which it contains by referring to it as "a unique book". Louis de Broglie is primarily a theoretical physicist, and it was through his careful and critical analysis, in the early 1920's, of the necessity to reconcile the granular and undulatory aspects of light that he was led to suggest the extension of the idea of the duality of waves and corpuscles to all elements of matter. He predicted the relationship $\lambda = h/p$ between the wave-length λ of the wave associated by wave mechanics with a corpuscle of momentum p, which was very soon afterwards verified experimentally. This same brilliant analysis and exposition de Broglie applies in this volume to the discussion of the formal opposition between the physics of phenomena on the large scale where the classical ideas of localization in space and time, of determinism, and of the individual object, are fully valid, and the physics of the atomic and corpuscular scale where, because of the quantum of action, these ideas are obscured or must be verified.

The original French edition appeared in 1947 and was entitled "Physique et Microphysique". Dr. Martin Davidson, who is to be congratulated on his excellent translation of this important work, has with the consent of the author made some alterations to the original text. Chapter 12, which was entitled "Un Glorieux Moment de la Pensée Scientifique Française", has been omitted completely, and Chapters 9, 13, 14 and 15 have been summarized. Also, since with the rapid progress in atomic physics during recent years some of the statements and data presented in the original French version are now incorrect or require modification, Dr. Davidson has where necessary added suitable explanatory notes at the end of the appropriate chapters. The contents consists of seventeen essays or lectures divided into three parts appropriately headed—science, scientific philosophy and history of the sciences.

In the first part, de Broglie describes the early development of our knowledge of the elementary particles of matter and how progress in this direction has transformed our theoretical conceptions of the constitution of nuclei and of the fields that assure their stability. Other chapters deal with the part played by light in the physical world; wave mechanics and electron diffraction; the concept of quantity in physics; and the formation of images in corpuscular optics.

The opening chapter in the second part, "The Revelations in Microphysics", is worthy of considerable study. Bohr's idea of 'complementarity' is given some emphasis, and the philosophical implications of atomic physics and wave mechanics are outlined. de Broglie is a modest man, but it is necessary for him to look back in retrospect on the origins of wave mechanics; thus, Chapter 8, which is devoted to personal memories on the beginnings of wave mechanics, is excellent reading and shows up clearly the deep insight to physical problems that de Broglie possesses. In later chapters the ideas of Zeno and Bergson on time and motion are considered in relation to the new physical concepts, and with regard to chance and contingency in quantal physics von Neumann's views are discussed in some detail. Finally, in the third part, de Broglie tries to emphasize the link between pure science and its applications; the moral problems introduced by the atomic era; and the grandeur and nobility of pure and disinterested science. He concludes the last chapter, "The Great Adventure", with the words: "In the work of science man has been able to show the force of his intelligence; if he wishes to survive his own successes, it is necessary that he should now show the wisdom of his will".

This is a book that every physicist should read and ponder over. S. WEINTROUB

THE COLLECTED PAPERS OF H. A. KRAMERS

Collected Scientific Papers

By H. A. Kramers. Pp. xi+969. (Amsterdam: North-Holland Publishing Company, 1956.) 45 Dutch florins; 90*s.*

THE world of physics has good reason to be grateful to the editor of these collected papers, N. G. van Kampen, and to the various Dutch funds and institutions which generously supported the publication of this monumental volume.

A number of Kramers's papers were published in not too accessible journals, but will now be readily available. Among those are his thesis, the paper on the Kramers–Kronig relations, and the papers on his renormalization theory (Como, 1937; Solvay, 1948). Indeed, the fact that modern mass- and charge-normalization procedures were anticipated by Kramers in his radiation theory of 1937 is only too little realized.

The papers are broadly arranged according to subject, and within each group chronologically. The first group contains the papers from Kramers's Copenhagen period on the quantum theory and later papers on quantum mechanics. It includes his paper in the *Philosophical Magazine* on X-ray absorption, the Kramers–Heisenberg paper, and the paper on the *W–K–B* method. It also includes his papers in the *Proceedings of the Amsterdam Academy* on the so-called symbolical method. The second group deals with paramagnetism and ferromagnetism. The last group is a mixed one. It includes his papers on quantum electrodynamics, the Kramers–Wannier paper on order–disorder, and the paper on charge conjugation in the Dirac hole theory.

It is impossible to do justice to this book in a short review. It shows better than any obituary could do the many-sidedness of Kramers's work as a physicist. Unfortunately, it was decided not to include Kramers's philosophical and popular papers. These show his wide understanding of the human aspects of physics. They are practically inaccessible, especially to those without a reading knowledge of Dutch, and a selection of them (in translation) would have been a very valuable addition. (His Leyden inaugural lecture, "Physicists as Stylists", was translated (*Naturwiss.*, 24, 297; 1935) and rewards the reader with a broad vista of physicists as human beings.)

His semi-popular book on early quantum mechanics, written in collaboration with Helge Holst, has long been available in many languages, and his text-book on the foundations of quantum mechanics is about to be published in an English translation, so that Kramers's complete works will now be readily available, apart from his popular papers.

TRENDS IN ANATOMICAL TEACHING

Lehrbuch und Atlas der Anatomie des Menschen

Von Dr. Fr. Kopsch. In zwei bänden. Band 1: Allgemeines, Skeletsystem, Muskelsystem, Gefassystem. Pp. viii + 736. 64.50 D.M. Band 2: Eingeweide, Nervensystem, Sinnesorgane. Pp. viii + 768. 64.50 D.M. Neunzehnte Auflage. (Stuttgart: Georg Thieme Verlag, 1955.)

These volumes have an interesting pedigree for the British reader. It was in 1870 that Carl Ernst Emil Hoffman prepared the first German edition of this work, which he based upon the seventh edition of Quain's "Anatomy". The Quain–Hoffman text was then, in 1892, taken in hand and revised by Dr. Rauber. The present editor, Prof. Fr. Kopsch, became responsible for the seventh edition in 1906, and has remained in charge of the work until this, the so-called nineteenth edition, so that he has had ample time in which to impress upon it to the full his own anatomical personality.

Printed on good-quality art paper, the two volumes between them contain more than fifteen hundred pages. The type is clear, the binding is robust, and the format of the volumes as a whole is a pleasing one. The illustrations have been conceived and executed on a generous scale. Many of them occupy an entire page, and they appear to have been drawn with great care, though Figs. 528 and 529, showing the segmental areas of skin innervation, seem to be somewhat at variance with what is generally accepted in Britain.

Vol. 1 begins with a general section (pp. 1–100) and then continues with osteology, arthrology, myology and angiology; Vol. 2 deals with splanchnology, the nervous system and the sense organs. The general section gives an account of the basic properties of the cell, and a description of the different cell types—including an estimate of 8 billion as the total number of cells in the human adult (excluding the blood cells). This section also includes a description of the body as a whole, a brief consideration of body build, various body measurements and an account of anatomical terms. In addition to the general histology contained in this section, the special histology of the various organs, beautifully illustrated, is given throughout the text together with the gross anatomy.

A review of an anatomical text-book is an appropriate occasion for recalling that anatomy is one of the oldest of the scientific disciplines, and that the publication in 1543 of the "De Corporis Humani Fabrica" of Andreas Vesalius was one of the great landmarks in the history of modern science. During the centuries which followed, anatomy has had its ups and downs, periods of stagnation alternating with periods of progress.

Towards the end of the nineteenth century, when the young and vigorous sister science of physiology broke away to enter upon a period of rapid expansion, most anatomists devoted their attention to the study of form, as opposed to function. But even when the study of anatomy was confined almost exclusively to the dead body, the boundary between these two facets of biology was never perfectly clear-cut, and in recent years has become blurred to an increasing extent. There has been an anatomical revival, which has steadily been gaining momentum, based on a variety of new techniques for the study of the living organism and its component tissues. As a result of this development, the fields of anatomical and physiological studies have tended to overlap more and more.

However, not all anatomists have welcomed the newer developments with the same degree of enthusiasm, or thought it necessary to incorporate them into anatomical teaching to quite the same extent. Prof. Kopsch takes care to emphasize in the preface that he is adhering in the main to well-tried morphological methods of presentation, and is concerned with form rather than function. But the changes in form which occur during life can only be studied intelligently against a background of function, and if one is too resolute in the avoidance of functional considerations, one is bound to lose much valuable information in the field of living morphology. Thus, to give but one example, there is no reference in the present work to cholecystography.

Subject to considerations of this nature, and within the author's self-imposed limitations, these volumes constitute an impressive tribute to the deservedly high standing of Prof. Kopsch in the anatomical world.

J. M. Yoffey

Old Fourlegs

The Story of the Coelacanth. By Prof. J. L. B. Smith. Pp. x+260+6 plates. (London and New York: Longmans, Green and Co., Ltd., 1956.) 21*s*. net.

THIS is a popular account of the discovery of the Coelacanth as a living fish. It is also a record of the intellectual agonies suffered by a sensitive man of science when confronted with a phenomenon which made nonsense of his previous academic training and experience. Smith tells not only of the way in which the first fish was brought to his notice and of the way in which he pursued the second but also of his investigations, which showed that this animal was no denizen of the deep, as suggested by many authorities, but lived in the reefs off the remote Comoro archipelago approximately midway between Portuguese East Africa and northern Madagascar.

Among the difficulties which Smith had to overcome before obtaining his second fish was getting permission from Prime Minister Malan to use a military aircraft for a quick and essential journey to Comores, and an excursion into diplomatic channels to persuade the French Governor of the Comores that the fish could belong to no other than Smith despite his South African nationality. Many of Smith's personal difficulties are dramatically described and a number appear to have been of his own devising. Against this, it is almost certain that the writing of yet one more chapter in the story of the natural evolution of animals would not have been made without his fanatical devotion to the Coelacanth. His relentless pursuit after factual evidence is worthy of the true man of science and it is good that Smith has set down a record of his fears and hopes and disappointments and triumphs as encouragement for others. The story is not well told but is so romantic in itself that the telling scarcely matters.

T. H. HAWKINS

Electric Dipole Moments

By Dr. J. W. Smith. Pp. vii+370. (London: Butterworths Scientific Publications, 1955.) 42*s*.

DR. J. W. SMITH has provided a sound, solid and comprehensive account of dipole moments, an important field which has gathered fresh impetus during recent years. The first three chapters of his book deal with the general physical theory, with the conventional method for measuring dipole moments, and with various unconventional methods, mostly recent. The headings of the remaining chapters are: general results; the origin of electric dipole moments; solvent effects; induction and mesomerism; dipole moments in relation to molecular structures and configurations; atom polarization; restricted rotation about single bonds; molecular association and molecular interaction. There is an appendix on wave mechanical principles, and a table of bond refractions.

On the whole, this is a good book: it is well written, well produced, and covers the subject in a very satisfactory manner. One could wish that the author were more critical, particularly in the sections on evaluation of results and on solvent effects: the general reader would find them tedious; the specialist would find them inadequate. The appendix on quantum theory is quite useless, and the space could have been used better in other ways; for example, the experimental section is marred by failure to quote the types of valve used in many of the circuits and the dimensions of the dielectric cells. The general accuracy of the measurements is nowhere properly discussed. The account of carbon monoxide and nitric oxides on pp. 112–4 is very confused.

However, these failings are not serious, and the book can be confidently recommended to all chemists who have any interest whatever in the subject. The price is not unreasonable.

M. J. S. DEWAR

Magnetic Materials in the Electrical Industry

By P. R. Bardell. Pp. 288. (London: Macdonald and Co. (Publishers), Ltd., 1955.) 32*s*. 6*d*. net.

THE intention of the author of this book is to help students of physics and electrical engineering, and also physicists and engineers in industry, to a fuller knowledge of magnetic materials, their properties and their applications. It also sets out to resolve some of the difficulties arising from proprietary names of materials and confusion among technical terms and units. Prof. James Greig, in a foreword, welcomes the book as relating engineering practice to scientific principles and physical phenomena.

The chapters on permanent-magnet and high-permeability materials describe the development of these materials and their ability to meet the requirements of various applications. The characteristics of many materials are presented in tabular form by type and maker's name. There are two chapters on the application of soft magnetic materials at power and communication frequencies; they include the properties of powder cores and ferrites. The effects of flux density and frequency on loss are well brought out, but the effect of saturation on wave-form is not considered. Various methods of measuring soft magnetic materials are described. Magnetic recording is also dealt with clearly and simply. The testing of materials by magnetic means is considered under the headings of magnetic discontinuity and of magnetic characteristic, and examples of each are described.

The principles of magnetic amplifiers and transducers and some typical equipments are described. At the end of each chapter is a list of references; an appendix contains a glossary of terms referred to in the text, and there is an adequate index. The tabulated information of the characteristics of magnetically hard and soft materials is well presented, and there are good illustrations of various items of equipment such as power transformers, telephone relays, choking coils and powder cores.

This book will be found most useful by students and others to whom the properties of many industrial magnetic materials are not readily available.

H. M. C.

Elizabethan Copper

The History of the Company of Mines Royal, 1568–1605. By Prof. M. B. Donald. Pp. vii+405+9 plates. (London: Pergamon Press, Ltd., 1955.) 60*s*. net.

THE history of metalliferous mining in Britain has not, as yet, received the attention it deserves, and it awaits an author who will deal with the subject comprehensively and as a whole. Meantime, an important contribution to the story has been made by Prof. M. B. Donald, who has brought to his task not only a practical interest in historical research, but also the necessary technical background acquired during a career that has embraced both the commercial and academic sides of technology.

This book tells, with much detail, the story of the opening up of copper mines in the Lake District in the sixteenth century, and of the formation of the Company of Mines Royal which was incorporated in 1568 to exploit these mines. In addition, the reader is given an account of the commercial and legal background, together with biographical details of the principal participants in the activities, including the technical advisers who came to Britain from Germany to superintend operations. The tale unfolded discloses that the promotion and exploitation of mines were carried out, in Elizabethan times, in a manner not very dissimilar from that employed to-day. A later chapter in the book describes the opening of copper mines in Cornwall during the same century.

Many manuscript sources, some new and unpublished, have been consulted in compiling this book, which is both an interesting and important contribution to the history of technology. It is likely to remain for a long time to come a standard source book for the field it covers. V. A. EYLES

Chemical Trade Names and Commercial Synonyms

A Dictionary of American Usage. By Williams Haynes. Second edition, revised and enlarged. Pp. vi+466. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1955.) 60*s.* net.

THE title of this book indicates its scope reasonably well, but the intention is to limit the terms listed to those of chemicals and chemical preparations sold industrially rather than by retail; pharmaceutical products, either as individual chemicals or compounded, are not included.

A trade name is accompanied by an indication of the American supplier and, ideally, the definition gives first, the composition and then the chief uses. There are gaps in definitions that could be filled; for example, Santowax P, described as a "coal-tar resin", is known to be *p*-diphenylbenzene, and the identity of Musk Tibetene has been published (Fuson, 1947). There are also obvious errors; thus methacrolein is stated to be *iso*butylene oxide, heptyl alcohol to be octanol and methionine to be sulphur-free. There is an occasional weird definition as, for example (p. 95), "hydrosulphite product free from heavy *m*-dianisidine", and there are double entries such as for methoxychlor, oxone and durene. There are innumerable printing errors, each petty in itself but aggravating in the aggregate, and there is more than one indication that at least some such errors have arisen from the setting of copy as received.

Much useful information has been collected here for anyone who has contacts, however indirect, with the American chemical market; but, as already indicated, there is plenty of room for improvement in detail. Moreover, does that market deal in acetic acid as "vinegar of Venus", in formic acid as "spirit of ants" and in carbon dioxide as "acid of air"? Maybe it does, since there is apparently still a call for woad. B. A. ELLIS

Quantitative Methods of Organic Microanalysis

By Dr. S. J. Clark. Pp. x+253. (London: Butterworths Scientific Publications, 1956.) 30*s.*

ON looking at the library of books on quantitative organic microanalysis, one would not say that there is a surfeit of literature, and so a new volume by a new author immediately arouses interest. By incorporating the latest methods with older proved ones, this book fills a much-needed gap, especially if allowance is made for the speed with which modifications are published in the journals. However, some of the methods are so new, and so much reference is made to "unpublished works", that for the moment they cannot inspire a great deal of confidence in them.

As the author has included both old and new methods in a book of only 250 pages, one gets the impression of a skimping of detail. For example, the use of nickel ammonium sulphate as an absorbent for ammonia is given on p. 93, but no reasons are stated for its choice. On p. 104, one is left guessing as to whether the hydrogen peroxide is neutralized before use, and boiled after absorption to destroy excess, as is done in the standard procedure. The first five chapters deal with the usual routine weighing, general apparatus techniques and ashing. Except for the inclusion of the Karl Fischer water determination, and ion exchange for determination of metals, they remain virtually unchanged. Six chapters are devoted to elementary analysis, and the following five to the determination of functional groups. Of particular interest is the inclusion of fluorine with the halogens, the direct determination of oxygen, and titrations in non-aqueous solvents.

The microanalyst is of necessity an individualist, and although he may not use completely any one particular method, he can obtain from this book much useful information to try out for himself. It is recommended for a place on the bookshelf. F. H. OLIVER

Photographie et Cinématographie Ultra-Rapides

Actes du deuxième Congrès International de Photographie et Cinématographie Ultra-Rapides, Paris, Septembre 1954. Présentés par Pierre Naslin et Jean Vivie. Pp. xxviii+456. (Paris: Dunod, 1956.) n.p.

THIS volume is a record of the second International Congress of High-Speed Photography held in Paris in 1954 and contains more than sixty contributions dealing with many branches of high-speed photography and cinematography and their applications. Each article begins with a summary in each of the three languages of the conference, English, French and German, and is printed in full in one of them.

The value of this volume lies not only in the wide field which is covered but also in the fact that the articles are authoritative, many being contributed by acknowledged experts in this field of photography. In addition to being a source of reference to modern techniques, this book will also be of great use to anyone searching for a method of recording for some new investigation. It is often by taking a technique which has been developed in reference to one particular subject and by adapting it to another that advances are made, and here one can see what methods are being used in fields of investigation which are very remote from each other.

On the whole, the volume is well produced; but a slightly more substantial paper might have resulted in better reproduction of some of the illustrations. The coloured plates, for which special paper has been used, are well produced. The index is not very adequate; but perhaps if a more elaborate one had been attempted the production of the book might have been delayed and this would have been undesirable for, as is well known, the third International Congress is to be held in September of this year in London under the auspices of the Department of Scientific and Industrial Research.

HUMAN PROBLEMS OF INDUSTRIAL COMMUNITIES

H.R.H. The Duke of Edinburgh's Study Conference on the Human Problems of Industrial Communities within the Commonwealth and Empire —to give it its full title—looked at first sight an intellectually unmanageable proposition. The intention was to collect about 280 members, ninety from the United Kingdom and the remainder from overseas, half managers and half trade unionists, for three weeks, of which the first and last period would be in Oxford and the centre ten days spent, in twenty groups, visiting factories and social institutions in twenty principal cities of England, Scotland and Wales. The members were not to be intellectuals or research workers, but men in the early prime of life actively engaged in industry either as managers or worker/trade unionists. The bill of fare for the Conference fell into four stages. First, the circulation, three months in advance, of twenty-five "Background Papers", dealing either with practical problems as seen by a practical man ("Stabilization of Labour in the Rhodesian Copperbelt", by Sir Ronald Prain), or with more general problems seen academically ("The Will to Work", by Prof. C. A. Mace; "Work and Community in a Primitive Society", by Prof. Raymond Firth). Second, a series of ten major addresses in plenary sessions at Oxford, with some very short group-discussion periods to enable the members to meet one another. Third, the "Study Tours", in which the whole Conference dispersed in groups of fourteen members with the addition of a specially selected United Kingdom chairman, each group spending about five days in a provincial city and its neighbourhood and four days in London. Fourth, a period of three days intensive group discussion in Oxford, followed by oral reports from groups and a general summary.

At first sight, the Conference ran with outstanding success. After more than two years of intensive preparation, the members, in almost exactly the planned proportions, and of very high quality, arrived in Oxford on July 8 and were swept through the programme, from the impressive opening ceremony in the Sheldonian to the final dinner in Christ Church on July 27, without a major hitch. All the incidental values (and they are not to be undervalued) were realized: the mixing of nationalities and industrial 'sides', the total absence of colour-consciousness, the sense of fellowship and common search. Nevertheless, it remains to ask three important questions: Was the subject-matter, so handled, manageable? Did the members absorb new ideas to any useful extent? What lasting effects can the Conference hope to have achieved?

Possible criticisms are obvious and formidable. It is acknowledgedly a difficult matter to hold the attention of such differing groups as sugar plantation workers in the Caribbean and Canadian electronic engineers. How could any programme the wit of man could devise suit both? Again, it is supposedly true that education, particularly via discussion groups, does not go very well when the gap in background and intellectual sophistication between the students is too wide—and it is hard to imagine wider gaps than those which existed in this Conference. Finally, the practical experience of the study tours was, of necessity, a rapid survey of certain problems of the United Kingdom, utterly unlike those of Pakistan or Sierra Leone or Johannesburg, and of necessity dimly comprehended and inaccurately interpreted.

Common Problems

These are formidable objections. Yet the conviction of a great number of intelligent members contradicts them flatly. My own answer to this conundrum was found in the recollection that industrialism is, in the full sense, a culture. It is so easy to recognize this about the past—historians and anthropologists speak readily of, say, pastoralism and the complex of religious, social and economic patterns of life associated with it. 'Industrialism', too, means more than certain manufacturing techniques; it has been based on a certain philosophy, it has raised certain political problems, it has set a certain social pattern wherever it has appeared. Examination of some of these associated effects of industrialization may be the best way of explaining why this diverse body of Conference members, from diverse backgrounds, in fact found a common language.

In the first place, the factory itself is a major and new political event. To hold some hundreds of men together, over long periods of time, in co-operation towards a single end, has only been achieved in history—on any wide scale—by three methods: slavery, military discipline or monastic discipline. The factory poses entirely new problems. From whence is the authority of 'the management' derived? What are its sanctions, and its limits? If we are to speak of leadership rather than authority, what are the common purposes between leader and led which can provide the continuing reason for consent? These are common problems "whether on the shores of Asia or in the Edgware Road". Within them lies the problem of personal and group satisfaction at work.

Again, and still in the political field, industrialization involves a shift of power away from old landowning and aristocratic groups; it means a rapid erosion of the influence of hereditary status (birth, chieftainship, caste) and the emergence of a new group of technical, administrative and professional leaders. This is true in Britain, and it is becoming clear in India (Mr. Tata explicitly commented on it in his address), in Africa and in Fiji. It is interesting that the newer societies, such as Australia, never greatly felt this problem, because industrialization has developed in almost pure form with no earlier culture to compete with. Moreover, not only does power shift, but also it tends to become centralized, both in the community and in government, by the growth of industrial combines and by the increasing need for State intervention and planning. This has been seen in Britain in developed form, despite our conscious efforts—not wholly unsuccessful—to retain and bolster local government and local initiative.

This leads directly to a third common effect. The industrial 'exchange economy' leads to a final break with the older subsistence economy based on the land. Once the 'worker' becomes wholly dependent on 'finding work', and has neither land nor tools of production to fall back upon, he is perilously dependent on the stability of the economy—the maintenance of 'full employment'. Far richer, but far more complex, the man-made industrial economy demands a man-devised fashioning of society—all the insurances against temporary breakdown which we call social security, diversification of industry, indeed every form of planned social control. Hence the growth of a planning and executive central State.

Three more common problems must be mentioned briefly, because all three occupied so much of the discussions in the Conference: the impact on family life, the change in the nature of community life, and the quest for social ideals. In certain ways they are connected. As both the mother and the younger members of the family are sucked into independent wage-earning employment, the authority of the head of the family weakens, the older people, once 'retired', tend to be pushed on one side, and ideals of individual personal development weigh more and more heavily against the institution of family and 'home'. So also the peculiar form of industrial urbanization in the big city swamps the institutions of village social life and is apt to leave a mass of atomized individuals instead of a social structure. Both these changes, so obviously connected with the needs of industry both for concentration and for mobility, raise the question of social ideals: Are the needs of production, the aim of material success, to dominate and exclude age-old values of personal and social life?

The Impact of Industrialization

It was around these common problems that the main addresses to the Conference fell. After the opening address by the Duke of Edinburgh—by common consent a brilliant and obviously personal contribution—with its emphasis on humility and study, and on the aims of a civilization rather than the wealth of an economy, Sir John Maud struck the keynote of the Conference work by his speech on "The Impact of Industrialization". Outstanding in my memory of this memorable address, and in its effect on the Conference, were a series of paradoxes. Industrialization can bring, said Sir John, more freedom and more slavery: more loneliness and more fellowship: more civilization and more barbarism. Which way the balance tilts hangs on the personal philosophy, courage, faith and effort of the myriad individuals within society.

Thereafter came a series of addresses, the titles of which show their drift. "The Varying Pattern of Industry", by Lord Citrine; "The Human Problems of Industry", by Mr. Waring, Mr. J. M. Campbell, Sir Alfred Roberts, Mr. J. Crawford, Colonel Grierson; "Everyday Relations of Industry and the Community Around It", by Sir Harry Pilkington and Dame Florence Hancock; "The Two Partnerships—Man with Man and Man with Nature", by Sir Harold Hartley. In the last period at Oxford the discussions were supplemented by five more addresses in a series of "Overseas Viewpoints": "The New Industrial Communities in West Africa", by Mr. R. K. A. Gardiner (Gold Coast); "The Future Responsibilities of Trade Unions", by Mr. A. E. Monk (Australia) (owing to illness, this paper was circulated in written form); "Industrial Problems in a Multi-racial Society", by Mr. H. F. Oppenheimer (South Africa); "Thoughts on the Industrialization of a Predominantly Rural Society", by Mr. J. R. D. Tata (India); "The Effects of Technical Change", by Mr. W. J. Bennett (Canada).

All these addresses were more than able; but beyond question, if we take the addresses of the Duke of Edinburgh and Sir John Maud as the first high points, Sir Harold Hartley's as the second, then Mr. Gardiner's speech, closely followed by Mr. Oppenheimer, was the third, and in certain respects, the highest. Speaking with the most palpable sincerity and controlled feeling, Mr. Gardiner put forward the thesis for equal respect for the human dignity of the individual of whatever race, religion or colour, as the only real basis upon which the future of the Commonwealth could rest. "The individual ought to feel that certain things cannot happen to him as a person, not because he belongs to a privileged group or race." "We can form a society on a set of rules; but if we intend to form a community—and that is what, to me, a Commonwealth means—that can only be formed on the basis of a common understanding or outlook, a common ethos. Is it going to be possible for us to develop this common outlook, to make it possible for us to continue to set an example to the rest of the world?"

"For *us* to continue . . ." Perhaps these words do not look startling in print; but from the speaker, on the occasion, they moved the whole Conference to an ovation reserved for no other speaker save the Duke of Edinburgh himself. Followed, as they were, by a practical, statesmanlike and liberal speech by Mr. Oppenheimer, tackling the problem of Southern Africa foursquare (and, if it had not been tackled, it would have been an abscess in the Conference), they confirmed finally a sense, already growing, that this Conference was not merely a successful façade but an event in which things of lasting importance were happening as day followed day.

Industry and Social Service

Each group of members, fifteen in number including their chairman, spent ten days 'on tour', seeing representative men and women in industry and social service in a very intensive programme based primarily on discussion, with only enough sight-seeing of factories or schools to give atmosphere and background. In fact, the discussion seems to have been admirably frank and full—several factories referred to it afterwards as more like an inquisition than a visit. Each group was given three subjects for special study, and the final reporting, dealing with these special subjects in groups and consecutively, covered the main field of the whole conference.

What came out of these reports? A remarkable unanimity in five or six directions. Smaller working groups where the supervisor really can supervise personally and the manager can manage; personal relationships and personal trust as a factor transcending all other 'incentives' and 'conditions at work'; independent social activity by the community, not managed by the factory; opposition to the employment of married women with young children; restoration of the central importance of family life; the need for spiritual values. When the oral reports are published, these will be some of the leading themes.

It is true that to many people these are platitudes. But fifteen years ago they were in the mouths, not often of 'practical men' but of the so-called intellectuals, social scientists, psychiatrists and anthropologists. It is of real importance that this is now the talk of practical men from all corners of the

Earth—trade unionists and managers alike. Ideas have moved not only out through society from their intellectual fountainhead, but outwards throughout the Commonwealth; and they are the same ideas, whether in Nigeria or Pakistan.

Writing fresh from the impact of this meeting, which developed an atmosphere of common effort which, in the Duke of Edinburgh's words, you could cut with a knife, I am bound to over-estimate the effects of this event. Yet that it was an event, with its own tiny place in the story of the Commonwealth, I am convinced. The members, when they return to the intrigues, the disappointments, the prejudices and the passion of real life in their countries (conferences are never real life) will carry back with them not only an experience of friendship—and that was abundantly evident—but also a reinforcement of faith and hope. Is anything of more value?

GUY HUNTER

PHYSICS OF GAS FLOW AT VERY HIGH SPEEDS

THE summer discussion meeting of the Physical Society was held in the University of Manchester during July 16–17 under the auspices of the Departments of Applied Mathematics and of the Mechanics of Fluids. The subject was "The Physics of Gas Flow at very High Speeds", that is to say, speeds so high that changes in kinetic energy are comparable with the energy required to produce interesting physical changes such as dissociation, ionization and substantial emission of radiation. The implications for the aerodynamics of man-made projectiles travelling at extreme speeds, and also of meteors, were included in the discussion. The shock tube, the principal research tool in this field, was discussed at length, both as regards design and instrumentation for use with very strong shock waves, and in connexion with the results so far discovered by its use. Prof. S. Devons, vice-president of the Society, presided over the meeting.

As Prof. M. J. Lighthill, of the Department of Mathematics, University of Manchester, said in his introductory remarks, the object of the meeting was to promote studies in a field where two great new scientific disciplines of the twentieth century meet and overlap. These disciplines are, on one hand, chemical kinetics, as grounded theoretically on the study of collision processes and experimentally on spectroscopy as interpreted by the quantum theory of radiative transitions; and on the other hand, fluid dynamics, as it has grown up since the discovery of the basic concepts of the boundary layer and the shock wave during the first decade of this century, using the wind-tunnel as the principal experimental tool. Neither subject had yet reached the dignified status of a science in the nineteenth century, when as Sir Cyril Hinshelwood has observed, chemical reactions were classified mainly into those that go and those that do not go, and when fluid dynamicists were divided into hydraulic engineers who observed things that could not be explained and mathematicians who explained things that could not be observed. In the great, and largely successful, struggles of the past fifty years to reach some sort of systematic understanding in both these two fields, the scientists involved were naturally disinclined to complicate their problems by introducing ideas from quite different disciplines. So until very recently it has been the rule for fluid dynamicists to know almost no physical chemistry, and physical chemists almost no fluid dynamics.

During the past five years, however, a movement has grown up with the object of making new advances by pooling the knowledge that has been acquired in these fields. To this end, fluid dynamicists have set themselves to learn about chemical kinetics and students of chemical kinetics have started to study fluid dynamics. These herculean labours have already begun to make important improvements in our knowledge of combustion processes, and a number of conferences have been held in this field. More recently still, external aerodynamics (that is, the study of flow around projectiles moving through the atmosphere) has reached the stage where this pooling of ideas is necessary. To mention an extreme example, it has been announced in the House of Commons that the Americans propose to shoot at Ascension Island from their missile-testing station in Florida. A simple computation of the elliptic orbit which such a missile would have to follow (after it has left the atmosphere and its rocket motors have burnt out) shows that it would have to re-enter the atmosphere with a speed of at least 6 km./sec. But a speed of half this would already be sufficient to cause considerable chemical changes in the air around a projectile. These changes would involve dissociation of oxygen and nitrogen molecules into free atoms, as well as the formation of nitric oxide. At speeds of 6 km./sec. the dissociation of oxygen near the front of the projectile would be nearly complete, and that of nitrogen well advanced. These changes may be expected to have important effects on the airflow about the body, and hence on the aerodynamic heating which is, of course, what constitutes the main difficulty of flight at these speeds. They constitute the main reason why aerodynamicists have been learning chemistry.

The reason for the converse process is the development of the shock tube, which physical chemists have found increasingly useful for studying fast gas reactions since Kantrowitz advocated its use for this purpose five years ago. Developed originally for studying the fluid dynamics of shock waves under conditions far more flexible than could be obtained in wind-tunnels, it has found additional use as a means of studying how reactions proceed in time after the pressure and the translational temperature of a gas mixture have been instantaneously raised by known amounts. For example, the shock tube has been used in this way to determine the rates of dissociation of iodine, bromine and nitrogen tetroxide. Since the shock tube is so useful both in this kind of work and in studying problems of very-high-speed aerodynamics, two of the five main lectures at this conference were devoted to it.

After giving this introduction Prof. Lighthill then proceeded to read his own lecture on the dynamics of a dissociating gas. He began by outlining the scientific advantages of starting, in such a difficult subject, by studying, both experimentally and theoretically, the behaviour of a pure diatomic gas capable of dissociation into free atoms. The theory falls naturally into three parts: equilibrium theory; quasi-equilibrium theory of the transport properties, including radiative transfer; and flow theory involving large departures from equilibrium.

The first part includes the fundamental thermodynamics and statistical mechanics of the atom–molecule mixture, and also the theory of the flow outside the boundary layer between a body flying at extreme speeds and the shock wave which travels ahead of it, in cases where equilibrium is reached behind this shock wave in a negligible time. Prof. Lighthill described the Busemann theory of this flow, in which the shock wave is wrapped around the body like a piece of paper around a parcel, and also the recent developments by Freeman and Chester in which second and third approximations to the flow pattern, based on Busemann's approach as a first approximation, have been found, yielding more accurate equations for the shape of the shock wave. He gave also an alternative theory of the flow near the stagnation point on a sphere, in which the only approximation used is the assumption of incompressible flow behind the shock wave. The good agreement between these two theories, based on the neglect of quite different features of the flow, in their region of overlap, gives one increased confidence in both.

Prof. Lighthill discussed briefly the kinetic theory of the diffusive heat transfer (stressing the importance of interdiffusion of atoms and molecules) and its application to the theory of the laminar boundary-layer near the front stagnation point on a bluff body, touched on the physical mechanisms of radiative transfer, and then turned to theories of flow involving large departures from equilibrium. Freeman had calculated the passage to equilibrium behind a uniform plane shock wave, an important feature of this process being the decrease in relaxation-rate as the translational temperature drops. He was now engaged in applying similar methods of calculation to the curved detached shock wave ahead of a projectile.

Mr. H. K. Zienkiewicz, of the Department of Mechanics of Fluids, University of Manchester, then gave a lecture on aerodynamics at extreme speeds. This was based on slides prepared to illustrate detailed flows which he had computed using tables of the composition and thermodynamic properties of air in dissociative equilibrium over a wide range of pressures and temperatures. He discussed plane shock waves and expansions in this way and various flows obtained by combining them, and ended by giving a theory for axisymmetrical flow around a cone. In all cases he made a comparison between the behaviour to be expected of air and that which would be predicted if changes in composition were neglected or if the specific heats remained constant.

The lectures on design and instrumentation of shock tubes were given by members of the High Speed Section of the Aerodynamics Division of the National Physical Laboratory, Teddington. Dr. B. D. Henshall first spoke of the reasons for the popularity of the shock tube as a means for producing flows with high stagnation temperature (of the order of ten or twenty thousand degrees). He described the elementary theory of the shock tube, and its modifications by the effect of the walls, stressing the importance of wall resistance to the turbulent flow in the neighbourhood of the contact surface, with its somewhat surprising effect of decelerating the shock wave but accelerating the contact surface itself. He described the use of hypersonic nozzles at the downstream end of shock tubes to attain very high local Mach numbers at the expense of low Reynolds number, and pointed out that, if these nozzles are to 'start' satisfactorily, an initial back-pressure of a fraction of a micron of mercury is necessary. He described shock tubes using more than one diaphragm, and discussed the factors influencing diaphragm design.

Dr. Henshall then described in detail the proposed 6 in. square shock tube at the National Physical Laboratory, and discussed how different aspects of problems of free flight at extreme speeds can be simulated, using the straight portion of the shock tube or the flow after one or two subsequent expansions. Dr. O. L. Schultz described the timing and triggering devices which will be used in this shock tube, the pressure and temperature gauges which are at present proposed, and the way in which the latter will be used to measure transient heat transfer rate. He also described a method of inferring overall drag by measuring the acceleration of a freely floating model.

In the subsequent discussion Mr. C. H. E. Warren, Royal Aircraft Establishment, Farnborough, described the design of the shock tube under construction there. He was against the use of multiple diaphragms and favoured the straightforward use of hydrogen as a driver, raised to high temperature and pressure by combustion with oxygen. He agreed with Dr. Henshall that valuable work on simulating flight at extreme speeds could be done if the stagnation temperature and Reynolds number were reproduced accurately, even though the Mach number in the experiment was far too low. Inaccuracy of Mach number might be got over by changing the geometry.

Mr. E. M. Dowlen, of the English Electric Co., Ltd., Luton, then described the parallel work going on in his laboratory. He stressed the convenience of using small tubes (for example, of 2 in. diameter), and agreed with workers at Teddington on the advantages of surplus gun-barrels as the material of the high-pressure sections. Later, Dr. R. Hide, of the Atomic Energy Research Establishment, Harwell, described the shock tubes in use there, and the work going on concerning the application of magnetic fields to the highly ionized gas behind a very strong shock wave.

A different aspect of gas flow at very high speeds was discussed in the lecture by Dr. J. G. Davies, of the Jodrell Bank Experimental Station, Manchester University. After a general account of the astronomy of meteors, he described the techniques for observing, visually, photographically and by radio echoes from their ionized trails, the entry of meteors into the atmosphere at speeds between 11 and 72 km./sec. He mentioned the importance of observations of the drift of meteor trails as a source of information on winds in the upper atmosphere.

Dr. Davies pointed out that almost all meteors are less than a centimetre in diameter and evaporate completely (owing to heat transfer by direct collision with atoms and molecules of the atmosphere) at altitudes where the mean free path is large compared with the diameter. He described a theory of this process, from which a theoretical expression for the variation of light intensity with distance along the meteor trail can be determined. In some cases this theory is inapplicable because fragmentation of the meteor occurs, leading to greatly increased radiation and quicker evaporation. Bodies large enough to enter the denser region of the atmosphere, where they acquire a compressed-air cap ahead of them which largely shields them from the direct blows of atmospheric molecules, are those producing trails much brighter than the brightest stars, and they are observed far too rarely for any systematic knowledge of their aerodynamics to have been found. The larger ones reach the Earth in the form of meteorites, which are mostly of irregular shape, often pitted with deep, roughly spherical holes. Prolonged discussion at the meeting of whether information concerning the aerodynamical experiences of these bodies can be found led to no very helpful conclusions.

The last lecture was by Dr. Wayland Griffith, of the Palmer Physical Laboratory, Princeton University, where much of the pioneering work with shock tubes was done under the direction of Dr. Walker Bleakney. Dr. Griffith has been studying in Britain for the past year. He described fundamental work on the experimental verification of the Rankine–Hugoniot equations for a shock wave passing through various gases, using their known equilibrium thermodynamics. This work shows, for example, that although the transverse vibrations of the carbon dioxide molecule are excited in such experiments with a relaxation time equal to that found from acoustic attenuation work, the longitudinal (valence) vibrations still remained unexcited after a time long compared with this (of the order of milliseconds).

Dr. Griffith discussed experimental determinations in shock tubes, by Davidson, Hornig and others, of dissociation rates, and gave theories, both of the chemical kinetics of dissociation, and of the fluid dynamics of the process which may be postulated to infer the rates from the experimental observations. He then described the work which had been done in Dr. A. R. Kantrowitz's laboratory at Cornell University on ionization produced by strong shock waves in argon. The observed time-delays before equilibrium ionization has suggested improved approaches to the kinetics of the ionization process. The luminosity of the shock front itself, which has sometimes been observed, is the result of impurities. The measurements of conductivity of a gas with high electron density has shown satisfactory agreement with theory.

In his concluding address Prof. Devons remarked on the impressive degree of collaboration between applied mathematicians, physicists, chemists and engineers which seems already to have taken place in this field. He emphasized, however, that an even greater degree of co-operation will be necessary, both if the maximum effectiveness for man-made projectiles travelling at extreme speeds is to be achieved, and if the shock tube is to be fully utilized for uncovering the secrets of high-speed gas reactions.

THE WEIZMANN INSTITUTE OF SCIENCE

TO mark the tenth anniversary of the foundation of the Weizmann Institute of Science, the Board of Governors, together with representatives of supporting groups in Great Britain, the United States, Canada and Switzerland, held a conference in London early in July.

The Weizmann Institute had its origin in the Daniel Sieff Research Institute at Rehovoth, a town about twelve miles south of Tel Aviv. The Sieff Research Institute had been set up in 1934 by Mr. and Mrs. Israel N. Sieff, of London, as a memorial for their youngest son, who had died the year before. Dr. Chaim Weizmann (1874–1952), with whom Mr. and Mrs. Sieff consulted before founding the Institute, assumed its direction and was responsible for its first scientific programme.

In 1944 a group of Dr. Weizmann's friends in the United States launched a project to mark his seventieth birthday and raised five million dollars for the purpose. It was then decided to establish the Weizmann Institute of Science, the Daniel Sieff Research Institute being retained as the parent unit.

The foundation stone for the expanded establishment was laid on June 3, 1946, and the Weizmann Institute was formally inaugurated and began functioning in November 1949. The Institute now covers an area of some ninety acres, with four large buildings in addition to the parent structure, the Sieff Institute, and an Institute of Physics in construction. Compared with the Sieff Institute's original staff of ten scientists and some twenty technical and administrative workers, there are now 130 scientists and more than 350 other personnel.

The recent conference was divided into five sessions. Two of these sessions were under the chairmanship respectively of Sir Francis Simon and Sir Solly Zuckerman, and dealt with the Institute's scientific interests.

The Institute engages primarily in research and has no teaching responsibilities, apart from the affiliation of several of its departmental heads to the Hebrew University in Jerusalem as visiting professors. Its main research interests are in the exact sciences—mathematics, physics, nearly all branches of chemistry, and some branches of biology. The desire has lately been expressed by scientific staff at various levels for the introduction of postgraduate teaching as a means of augmenting Israel's reservoir of trained professional man-power and also as a stimulus to their own work. As a result of a recommendation of a Committee which was set up under the chairmanship of Sir Ben Lockspeiser, the Board of Governors has now decided to provide more opportunities for postgraduate training than were available in the past. This Committee also recommended "that the provision of special courses as a useful service for the country, as, for example, in the fields of radio chemistry, plastics chemistry, electronic computing and numerical analysis, be encouraged within the capacity of the Institute". Some time ago the U.S. Government decided to include support of the Radioisotope School at the Weizmann Institute, for training professional men in the use of isotopes, as part of a series of grants it was making for higher learning and research in Israel.

In addition to the heads of departments of the Institute who came from Israel, the conference was attended, among others, by Prof. P. M. S. Blackett, London; Prof. E. B. Chain, Rome; Prof. Louis Fieser, Harvard University; Prof. H. A. Krebs, Oxford; Sir Ben Lockspeiser; Prof. David Rittenberg, New York; and Sir Robert Robinson, London. Prof. Saul Adler, of the Hebrew University at Jerusalem, and Prof. S. G. Zondek, of Tel Aviv, attended in their capacities as members of the Institute's Board of Governors.

In addition to the resolution extending postgraduate teaching, the Board of Governors dealt with and decided upon certain administrative reorganization and the consolidation of the financing policy.

When eventually put into effect, the postgraduate teaching curriculum will be of great advantage to Israel, which has still to develop and broaden this aspect of its higher learning.

OBITUARIES

Sir Henry Guy, C.B.E., F.R.S.

BRITAIN has always been rich in engineers whose interests lay in the field of practical construction. It has never been quite so prolific in engineers concerned with engineering science. Although in recent years ill-health put a severe restriction on his activities, the death on July 20 of Sir Henry Guy has removed one from the smaller band of those who took an active and prominent part in the encouragement and organization of engineering research.

His interest was no theoretical interest. It was founded on a wide practical experience as an engineering designer. For more than twenty years he occupied the responsible position of chief mechanical engineer to the Metropolitan-Vickers Electrical Co., Ltd., where, in the quest for ever-increasing thermal efficiency, he designed steam turbines which were not only notable advances in regard to the steam pressures and superheat temperatures that were used, but also in regard to the size of the units. The 100,000-kW. turbo-generator which is now accepted as the standard unit for large power stations had already been designed by Sir Henry Guy and constructed by his Company during the 1930's. When the Soviet Government invited competitive designs for a turbo-generator unit to be used as a basis for the development of power stations in the U.S.S.R., it was his design put forward by Metropolitan-Vickers that won the award and the contracts against world-wide competition.

No one was better able to assess the gaps in our knowledge of engineering science than Sir Harry, as his opinion was fortified by his recollection of those many occasions when faith in his own intuition had to replace the experimental knowledge that was wanting.

When the Advisory Council of the Department of Scientific and Industrial Research, of which Sir Henry Guy was a member at the time, considered during the last year of the Second World War how the pattern of research should be developed in Britain, the need for more research on engineering subjects was specially emphasized. A committee under Sir Henry's chairmanship was set up to consider what practical action should be taken, and it was the recommendation of the Guy Committee that led to the foundation of the Mechanical Engineering Research Laboratory now sited at East Kilbride.

No one better could have been chosen as chairman for this purpose. His wide and detailed knowledge of engineering in its many branches made him visualize the sections into which research on fundamental science could be divided without multiplicity, and his guidance was invaluable. The creation of the Mechanical Engineering Research Laboratory became one of his principal interests in later years, and the fact that the pattern of its organization has not been changed since it started has confirmed the wisdom of his views and outlook.

Sir Henry Guy was naturally chosen as the first chairman of the Mechanical Engineering Research Board, and his kindly and tolerant manner in the chair and the sincerity of his desire to convert those who differed from him, or to be himself converted, helped the new organization to surmount successfully its teething troubles. Even during the period when his health was causing anxiety, nothing gave him greater pleasure than to hear from time to time of its success.

He served as secretary of the Institution of Mechanical Engineers during the period 1942–51.

A. MCCANCE

Mr. C. F. Charter, O.B.E.

CECIL FREDERICK CHARTER died in London after a brief illness on January 27. He was then director of Soil and Land-Use Survey in the Gold Coast. That country has lost a good friend, a good organizer and an outstanding scientist.

Charter was educated at the Lowestoft Secondary School and at Trinity Hall, Cambridge. After teaching at the Tientsin Grammar School in North China and at the Antigua Grammar School, Charter accepted an invitation to undertake a study of the soils of Antigua and Barbuda. Charter's report on the soil survey of Antigua and Barbuda published in 1937 was reprinted in 1947; in collaboration with P. E. Turner he published in 1939 observations on soils of sugar estates in Trinidad. During 1933–44 he was local scientific officer of the Antigua Sugar Cane Investigation Committee. In 1940 he visited British Honduras and wrote an illuminating report on the soils, many of which are impoverished by long exposure to heavy rain. Charter described as a maturity sequence the soils formed on non-calcareous alluvium of various ages. The alluvium covers a wide area and carries swamp forest, well-drained broad-leaf forest, conifers or poor savannah. Of these, the last two indicate moderate or severe impoverishment accompanied by development of a heavy, feebly permeable, brightly mottled subsoil.

In 1944 Charter was appointed soil chemist in the Gold Coast Department of Agriculture and worked in the West African Cocoa Research Institute. In 1949 he was promoted chief soil scientist of the Soil Survey Division, Department of Agriculture. In 1951 he was made director of a newly created Department of Soil and Land-Use Survey and was made O.B.E. He paid brief visits to the Belgian Congo, South Africa, Tanganyika and British Guiana in

1948–50, and in 1955 made an extensive study tour of the United States of America under the auspices of the Foreign Operations Administration.

In the Gold Coast, Charter developed a new technique in soil survey, employing methods adapted from those used in ecological surveys. Soil, vegetation and land-use were sampled or recorded at regular intervals along traverse lines and at regular intervals across the grain of the topography. Soils were mapped by topographical associations, but within each of the latter, sample strips a mile long by a quarter mile broad were mapped in complete detail to illustrate the soil, vegetation and land-use patterns occurring. Such work involved the use of large numbers of semi-skilled local assistants, the majority of whom Charter had to train himself.

One important detail of the procedure evolved by Charter was the orderly preservation of samples of soil and rock and the regular comparison of each day's findings with the selected standard samples. He was fortunate in that all his African junior assistants could read and write English; their work, however, was closely checked by those with better education or longer experience. The work was done with accuracy and enthusiasm and was generously supported by the Gold Coast Government, which constructed at Kumasi excellent laboratories and offices for Charter's department. At the time of his death, the department had an establishment of some twenty professional staff and 150 junior technical assistants of varying grades.

At the Cocoa Conference of 1949 Charter described the principal cocoa soils of the Gold Coast and discussed the phenomenon of soil creep occurring there and in Central America and the West Indies. After a visit to Tanganyika in 1950, he came to realize that many tropical soils were not truly sedentary but had developed in 'drift' parent materials. In a paper submitted to the Conference of the Consultative Committee for Tropical Africa on the mechanization of agriculture (Entebbe, 1955), Charter advocated bush fallows for maintenance of fertility in peasant agriculture. In an important paper presented at the Cocoa Conference of 1955 he noted that in the Gold Coast cocoa had failed to survive on acid soils ('oxysols') deficient in divalent bases, but had survived on the less acid and more fertile 'ochrosols'. He stressed the importance of including magnesium in fertilizer trials with cocoa. Charter associated the 'oxysols' with the reddish-yellow latosols of Kellogg and Davol (1949). He noted that the relatively infertile 'oxysols' are formed, where annual rainfalls exceed 70–80 in., from the weathering products of highly siliceous rock (quartzites) or from those of pyritiferous sediments which set free sulphuric acid during decomposition. In fact, appreciable amounts of sulphate in the subsoil of Gold Coast 'oxysols' had been found by the analyses of Charter's colleague, A. S. de Endredy (unpublished observation). A brief statement of Charter's views on the broader aspects of soil classification is given in the Proceedings of the Fifth International Congress of Soil Science (4, 497–499). A further account of Charter's views has been prepared for the Sixth International Congress of Soil Science by his colleague, H. Brammer.

Charter was born on December 4, 1905. A son and daughter, children of his first marriage, survive him.

HERBERT GREENE

NEWS and VIEWS

Metallurgy at Leeds : Prof. N. J. Petch

THE Department of Coal, Gas, and Fuel Industries with Metallurgy in the University of Leeds is to be re-organized into the three Departments of Fuel, of Chemical Engineering and of Metallurgy. Collectively they will form the Houldsworth School of Applied Science. Dr. N. J. Petch, at present reader in metallurgy, has been appointed to the new chair of metallurgy created during this re-organization.

After taking a degree in chemistry at Queen Mary College, London, in 1936, Dr. Petch spent a year studying engineering and then read metallurgy at the University of Sheffield, where he took his B.Met. in 1939 and was awarded the Mappin Medal. This varied training was completed by three years as a research assistant in the Crystallographic Department at the Cavendish Laboratory. His researches during this period culminated in papers on the positions of the carbon atoms in cementite, austenite and martensite. Dr. Petch then went to the Royal Aircraft Establishment, where he organized a new section of the Metallurgy Department, dealing with X-ray diffraction problems and routine radiography. He also began to take an interest in the field of fracture in metals, with which his name is now particularly associated. Initially this interest was stimulated by investigations of the mechanism of the hydrogen embrittlement of steels; but during the period 1946–49 which Dr. Petch spent in the Cavendish Laboratory with the team led by Dr. E. Orowan, his interests widened to include many fundamental aspects of fracture. Since 1949, when he was appointed reader in metallurgy in the University of Leeds, Dr. Petch has continued his studies of fracture and has published many important papers in the field. A problem common to all university departments teaching the applied sciences is to maintain an adequate balance in lectures between the rapidly expanding new knowledge and the established classical material. Dr. Petch, who is responsible for the teaching courses in metallurgy, has, during the tenure of the readership, carried out a careful re-organization to maintain the balance.

Geography at Liverpool : Prof. R. W. Steel

MR. R. W. STEEL has been appointed John Rankine professor of geography in the University of Liverpool as from January of next year, a post which has been vacant since the death in 1955 of Prof. W. Smith. Mr. Steel has spent his academic life in Oxford. He was an open exhibitioner of Jesus College, Oxford, and while still an undergraduate won the Royal Geographical Society's Essay Prize in 1936. In 1938, he was Draper's Research Scholar and carried out some research work in Sierra Leone. He made a second expedition to West Africa, jointly with an economist and an anthropologist, during 1945–46, and has recently returned from a further visit to Central Africa and East Africa. He has for many years been lecturer in Colonial geography in the

University of Oxford, and was elected a Fellow of Jesus College in 1954. He is the author of a number of papers dealing with various problems of African geography, and no doubt will be able to maintain his connexion with Africa when he takes up his new post.

University of Poona : New Building for Chemistry

THE opening of the new building of the Chemistry Department of the University of Poona by Pandit Jawaharlal Nehru on August 1 marks the first stage in the development of the University in the old Government House at Ganeshkhind, Poona-7. The University has built this department at a cost of Rs. 4 lakhs, and though it is still incomplete, the Government of India has agreed to pay two-thirds of the cost to complete the building by addition of the lecture halls. The Ranade Industrial and Economic Institute has been shifted to one wing of the new building. Through the gift of Rs. 3 lakhs from the Government of India, the laboratory is equipped with up-to-date apparatus and equipment for research and the training of postgraduate students in X-ray diffraction, magnetochemistry, ultrasonics, dielectric work, electrochemistry, absorption and fluorescence spectra, optical dispersion, microchemistry, chromatography, chemistry of sugars and gul, enzymes, and chemical instrumentation. There are well-equipped workshops and ample stores. The Government of India has awarded one national research fellowship of Rs. 400 a month and three senior fellowships of Rs. 200 a month. Six University research fellowships and two Shembekar scholarships have been awarded for Ph.D. students. During the past five years six students in the Department have obtained the degree of Ph.D. and twelve that of M.Sc. by research. Ninety students gained their M.Sc. by examinations in different branches of chemistry. More than fifty research papers have been published both in India and abroad. Five students are carrying out postgraduate research for their D.Sc., twenty-five (including six women) for their Ph.D. and five for M.Sc. (by research). There are at present 104 students in the postgraduate classes, twelve of whom are women.

Belgian Youth Federation for the Study and Protection of Nature

A BELGIAN YOUTH FEDERATION for the Study and Protection of Nature, a section of l'Entente Nationale pour la Protection de Nature, has recently been founded in Brussels. This organization, which will receive both material and moral assistance from l'Entente Nationale, will be run entirely by young Belgians between the ages of twelve and twenty-eight. The new Federation is also under the patronage of the International Union for Conservation of Nature and Natural Resources, which, since its foundation in 1948, has had its headquarters in Brussels. The aim of the Federation is to affiliate all youth societies throughout Belgium which share the same objectives, and thus Belgium will be able to send a more fully representative delegation to the camp which is being held in Austria this month when a federation on a larger scale, the International Youth Federation for the Study and Protection of Nature, will be founded under the auspices of the International Union for the Conservation of Nature and Natural Resources. The new international organization is a direct development of the International Youth Camps for the Study and Protection of Nature, to which the Union has each year given its sponsorship and its financial support, sometimes with the aid of Unesco. At present, thirteen European countries are participating.

Commercial Irradiation of Diamonds

THE United Kingdom Atomic Energy Authority has decided to accept requests for the irradiation of diamonds for commercial purposes, so far as other demands on the available irradiation facilities permit. In the past, the Authority has only consented to irradiate small quantities of diamonds for fundamental research purposes. Charges for this new service will be fixed by arrangement. The general phenomenon of irradiation-induced colour changes in gems was first discovered more than fifty years ago when effects of this kind due to radiations from naturally radioactive substances were first observed. Radiations from particle-accelerating machines, nuclear reactors and artificial radioactive isotopes may now be used to induce these effects. Diamonds irradiated inside a nuclear reactor are coloured green, and subsequent heat treatment may change the colour to brown ; on the other hand, the action of radiation from particle-accelerating machines may induce a blue or blue-green colour. Diamonds irradiated in a nuclear reactor become temporarily radioactive, but this radioactivity decays to insignificance within a few days. Inquiries should be addressed to the Technical Irradiation Group, Isotope Division, A.E.R.E., Harwell.

Employment of Chemists in Great Britain

AN analysis given in the *Journal of the Royal Institute of Chemistry* of the 8,555 entries in the 1954 edition of the Register of the Royal Institute of Chemistry, which were sufficiently complete for the purpose, indicates that the proportion of chemists employed by industrial firms has fallen to 58 per cent compared with 60·3 per cent in 1948. Government departments and nationalized industries, excluding the Department of Scientific and Industrial Research and the research associations, employed 13·8 per cent in 1948 and 13·2 per cent in 1954, the new intake being mainly to the Atomic Energy Authority : the percentage in the nationalized industries has increased from 3·6 in 1952 to 3·9 in 1954, and in the Department of Scientific and Industrial Research and the research associations from 4·6 to 5·1. The percentage engaged as public analysts and in consulting work rose from 3·5 in 1948 to 4·4 in 1952 and is now 3·5. The most notable increase since 1952 is in the percentage of technical college teachers—from 4·2 to 5·8 per cent—but the proportion in universities shows little change, and that in schools continued to decrease and is now 3·5 per cent. Entries for those resident outside Great Britain and Ireland were disregarded.

Oil Consumption in Britain during 1954 and 1955

THE Petroleum Information Bureau has published a booklet on the "U.K. Petroleum Industry Statistics relating to Consumption and Refinery Production, 1954 and 1955" (pp. 9 ; from the Bureau, London ; 1956) which shows that in 1955 a record was set up in oil consumption in Britain. The total inland consumption of petroleum products (exclusive of bunkering ships engaged on foreign trade) was 23,237,144 tons compared with 21,044,243 tons in 1954, an increase of more than 10 per cent. Demand for oil for central heating totalled 847,710 tons and has more than doubled during the past five years. Motor spirit consumed was 6,240,391 tons, 5 per cent above the 1954 figure. The booklet shows that sales of premier-grade petroleum were up by 10 per cent over standard grades, which showed a decline on the previous year. The growing popularity of diesel-engine commercial vehicles is revealed by the fuel consumption of the diesel-engined road vehicle ('Derv'), which increased by 188,000 tons in 1955; despite the much-criticized restrictions on major highway construction in Britain, asphaltic bitumen, so commonly employed in road-surfacing, actually showed a 7 per cent rise in consumption over the previous year.

A Medieval East African Coastal Civilization

The Rev. Gervase Mathew contributes to the May number of *Man* an interesting article on some early cultures of the East African littoral. To-day the whole region is under the influence of Zanzibar; but during the seventeenth and eighteenth centuries—between the fading away of the power of Portugal and the rise of Zanzibar—there existed a number of town settlements which were nominally Islamic in religion and influenced at least in part by South Arabia. Formerly, they have been classed as medieval Persian settlements; but Mathew is convinced that they represent a series of small autonomous Swahili States, oligarchic in their social structure, and using a currency of beads and rolls of cloth when trading in ivory and slaves. Did some of the Southern Rhodesian gold pass that way? Many of the buildings and their decoration and contents are impressive, and indicate wealth and a high degree of culture. Naturally, the influence of the Portuguese, who with the Spanish occupied the area from 1592 until about 1637, was considerable. But even before their arrival it would seem that there had existed an important series of townships in the region, as these are described in the early Portuguese annals. There were great walled cities and a population both dark (African) and white (Persian ?), the latter being the ruling caste. It is to be hoped that the author will some day write a monograph on the subject. But before this can be done, excavation will have to be undertaken at a number of key sites, and in the meanwhile every effort should be made to preserve as far as is possible the monuments which have survived.

Research on the Formation of Hurricanes

The spring number of *Oceanus*, a magazine published quarterly by the Woods Hole Oceanographic Institution, Massachusetts, for distribution to the associates of the Institution and others interested in oceanography, is devoted to meteorology and includes an article by the director of the Institution, Dr. C. O'D. Iselin, on projected research into the formation of hurricanes. Dr. Iselin describes an ingenious theory, which it is hoped to investigate on voyages in the converted 125-ft. cutter, *Crawford* (see *Nature*, July 28, p. 181). The theory is that the essential precursor of a hurricane is a period of abnormally light winds in a part of the northern half of the trade-wind belt in which sea-surface temperature exceeds 27° C. These light winds mean that so few large sea-salt condensation nuclei would form that less than the usual number of the cumulus clouds would precipitate rain, leading to development of unusually high humidity in the lower atmosphere. It is then supposed that an 'easterly wave' disturbance moves along in the trade winds, stirring up the sea and producing many nuclei and stimulating convection by release of latent heat. The intense convection then produces a whirl in the usual way. Dr. Iselin envisages that, if the theory is true, it might be possible, by maintaining random convection in the early stage, to stop the development of the abnormally high humidity and so prevent hurricanes from forming.

Freshwater Biological Research by a School-boy

The magazine of the Oundle School Natural History Society contains a useful comparative study by a school-boy, M. J. Fenwick, of the biology of species of *Asellus*, *Eucrangonyx* and *Gammarus*. These show that *Asellus* seems to favour almost any kind of water, but it is most frequently found in deep, almost stagnant water among plant debris; *Gammarus* favours very shallow and fairly swift water, usually with a sandy or shingle bottom; and *Eucrangonyx* favours a deeper, almost stagnant pond or pit, where there is plenty of shelter from bright daylight. Experiments showed that *Asellus* survives in water with a low oxygen concentration; *Eucrangonyx* can survive in water of almost any oxygen concentration; while *Gammarus* only survives in water of a very high oxygen concentration. *Eucrangonyx* appears to be strongly negatively phototropic, and *Gammarus* and *Asellus* are slightly negatively phototropic. Another series of experiments showed that *Asellus* is quite tolerant of any temperature from 0° C. to 30° C. *Eucrangonyx* is not quite so tolerant and only survives in temperatures between about 5° C. and 20° C.; and *Gammarus* is much less tolerant and will only survive in temperatures between about 10° C. and 20° C.—considerably lower than the temperatures tolerated by *Asellus* and *Eucrangonyx*. The observations show that each animal fills its ecological niche, and that the three are very rarely found together.

Recent Investigations of Cocoa

There was a time, not so very long ago, when new research information about the botany and horticulture of cocoa (*Theobroma cacao*) was relatively scanty and hard to come by. That time may now be said to have receded into the past. During recent months several full and important reports have appeared, including the Annual Report of the West African Cocoa Research Institute for 1954–55 (Crown Agents, 4 Millbank, London, S.W.1; 5*s*.), a Report on Cacao Research, 1954 (Imperial College of Tropical Agriculture, Trinidad, B.S.I.; also from the London Office, 40 Norfolk Street, W.C.2; 12*s*. 6*d*.), the Proceedings of the West African International Cacao Research Conference, 1953 (Crown Agents; 12*s*. 6*d*.), and the Cocoa Conference, 1955 (The Cocoa, Chocolate and Confectionery Alliance, 11 Green Street, London, W.1). From these several publications a comprehensive impression of the very considerable research effort that is now being devoted to all aspects of this important and valuable tropical crop may be obtained. The subject-matter ranges from such topics as soils and fertilizers and vegetative propagation by novel methods, to breeding and selection, the control of fungal and virus diseases and pests, and the processing of the eventual product, the cocoa bean.

Factors in Cell Division

THE importance of nucleic acid in growth and cell division is becoming increasingly recognized. Where division in permanent cells has been induced by the application of auxin, there appears to have been an attendant acceleration of nucleic acid synthesis. A. K. Sharma and A. Mookerjea (*Bull. Bot. Soc. Bengal.*, 8, 24; April–Oct. 1954; issued Dec. 1955 as Acharya G. C. Bose Centenary Commemoration Volume) have attempted to explore the relationship of nucleic acid to cell division and to overcome the difficulties of the penetration of cells by the large nucleic acid molecule, by growing onion root tips in solutions in which the constituents of nucleic acid, or their allies, were present, singly and in different combinations. Some fifteen different sugars, four bases (uracil, guanine, adenine and thymine) and ammonium phosphate were used in different concentrations and combinations. The results, obtained after periods of treatment of 1–168 hours, are set out in considerable detail. Counts of polyploid prophases and metaphases were taken from each root-tip specimen after appropriate treatment, and various other nuclear abnormalities were recorded. Practically all the sugars had some effect in inducing division in differentiated cells, but lævulose proved the most active in this respect. In general, however, no correlation was established between the nature of the chemical used and the induction of division. The significance of the results obtained is discussed in some detail.

Research Defence Society

WHILE a great deal is known about anti-vivisection societies, not so much is known about the Research Defence Society. This Society was founded in 1908 by Stephen Paget and exists to "make known the facts about experimental research involving the use of animals and the conditions and regulations under which animal experiments are conducted in the United Kingdom; to emphasize the importance of such experiments to the welfare of mankind and animals and the great saving of human and animal life and health and the prevention of suffering already due to them; and to defend research workers in the medical, veterinary and biological sciences against attacks by anti-vivisectionists". The Society is pledged not only to make known the facts of medical research and the part played in it by animal experiments but also to ensure that full use is made of medical discoveries of benefit to mankind and animals. It is therefore producing a series of pamphlets which will emphasize the need for making use of medical knowledge gained. The first of these pamphlets will be entitled "Vaccination against Poliomyelitis"; others will deal with diseases the comparative rarity of which to-day has made people dangerously complacent or the defeat of which is in the nature of a containment rather than a total elimination; diseases like diphtheria, smallpox, tuberculosis, diabetes and many others. With the publication of the pamphlets, the Society's journal, *Conquest*, will no longer appear quarterly but will be produced at least once a year.

The American Academy of Arts and Sciences

THE following, among others, have been elected foreign honorary members of the American Academy of Arts and Sciences: Prof. M. J. C. R. Courrier, professor of experimental morphology and endocrinology in the Collège de France, Paris; and Sir Geoffrey Taylor, Yarrow research professor of the Royal Society. The following have been elected officers of the Academy for 1956–57: *President*, J. E. Burchard, dean of the School of Humanities and Social Studies, Massachusetts Institute of Technology; *Vice-President for Class I* (Mathematical and Physical Sciences), J. H. Van Vleck, dean of engineering and applied physics, Harvard University; *Vice-President for Class II* (Biological Sciences), H. Hoagland, director of the Worcester Foundation for Experimental Biology; *Vice-President for Class III* (Social Arts and Sciences), D. F. Edwards, chairman of the Board, Saco-Lowell Shops, Boston; *Vice-President for Class IV* (Humanities), W. F. Twaddell, professor of linguistics, Brown University; *Secretary*, B. H. Billings, vice-president and general manager of Baird Associates, Cambridge, Mass.; *Treasurer*, T. B. Adams, treasurer of the Sheraton Corporation, Boston; and *Librarian and Editor*, W. M. Whitehill, director of the Boston Athenæum.

The Institution of Mining and Metallurgy

MR. G. KEITH ALLEN, reader in mining in the Royal School of Mines, London, and formerly resident director and chief engineer of the West African Gold Corporation, Ltd., has been elected president of the Institution of Mining and Metallurgy for 1957–58. Mr. Allen, who is a graduate in mining and metallurgy of the University of Melbourne, has spent most of his professional career with mining concerns in various parts of Africa. Mr. B. W. Kerrigan has been appointed secretary of the Institution of Mining and Metallurgy and will take up his duties at the beginning of this September. Since 1953 Mr. Kerrigan has worked in the planning office of the Imperial College of Science and Technology, London, and has been responsible for much of the administration of the extensive scheme for the expansion of the College.

The Society for Applied Bacteriology: Officers

THE following have been elected officers and members of committee of the Society for Applied Bacteriology: *President*, Dr. M. Ingram; *Secretary*, G. Sykes (Microbiology Division, Boots Pure Drug Co., Ltd., Nottingham); *Treasurer*, C. S. Miles; *Editors*, Dr. S. E. Jacobs and Dr. L. F. L. Clegg; *Publications Manager*, E. A. Whitlock; *Advertising Manager*, E. J. Mann; *Committee*, Dr. Ella M. Barnes, Dr. C. A. E. Briggs, J. W. Egdell, L. D. Galloway, H. B. Hawley, J. Liston, W. H. Pierce, C. A. Scarlett and Dr. Helen R. B. White.

The Animal Health Trust: Awards

THE Animal Health Trust has awarded research training scholarships for 1956/57 to the following: Miss J. A. Bailey, for work on parasites, at the Imperial College of Science and Technology, London; R. S. Anderson, for work at the School of Veterinary Medicine in the University of Glasgow on the problem of metabolic disease in animals and, in particular, the electrolyte/water balance in animal tissues; J. W. Boyd, to study for Part II of the Tripos Examination in Pathology at the University of Cambridge preparatory to undertaking research into metabolic disease of animals; Muhammad Irfan, for research at the Royal Veterinary College, London, on the blood picture of dogs, with particular reference to tumours and leucosis conditions; Miss S. R. Wooldridge, to study problems connected with the effects of radiation upon cells in tissue culture, paying particular attention to changes concerned with cellular division and multiplication and their late application to cellular pathology. The Trust has also awarded Evans final-year studentships to the following: P. G. H. Mann (Royal Veterinary College, London), K. Brown (Royal (Dick) Veterinary School, Edinburgh), M. Fussell (University of Cambridge), E. C. Pickering (University of Glasgow Veterinary School), J. McC. Howell (University of Liverpool) and P. L. Doherty (Veterinary College of Ireland).

Announcements

The Smithson Research Fund Committee of the Royal Society and the University of Cambridge has awarded the Smithson Research Fellowship to Dr. Anita I. Bailey, of Newnham College, Cambridge. Dr. Bailey, who is a graduate of the University of Witwatersrand, South Africa, is to carry out an investigation, in the Department of Physical Chemistry, University of Cambridge, on the surface energy of some solid materials and of the variations in this quantity which may occur when physical conditions are varied.

The twenty-third general meeting of the Society for General Microbiology will be held in the University of Exeter during September 20–22. Sessions for reading original papers will be held on September 20. The proceedings on September 21 will consist of a symposium on "Plankton".

The Mechanical Engineering Research Laboratory (Department of Scientific and Industrial Research) at East Kilbride, Glasgow, is to hold its first open days during September 20–21. Applications for invitations, stating which day is preferred, should be sent to the Director.

The British Mycological Society will hold its "Autumn Foray" this year in Sheffield during September 6–12. The meeting will be centred on the University Hall for Women, Endcliffe Vale Road, Sheffield 10, where a workroom is available. Application forms and further information can be obtained from Dr. J. Webster, Botany Department, The University, Sheffield 10.

The annual conference of the Society of Leather Trades' Chemists will be held in the University of Leeds during September 21–22. During the meeting the seventh Procter Memorial Lecture will be given by Dr. G. W. Kenner (University Chemical Laboratories, Cambridge), his subject being "The Present and Future Scope of Peptide Synthesis". Further information can be obtained from the honorary secretary of the Society, G. H. W. Humphreys, Forestal Central Laboratories, Harpenden, Herts.

An international colloquium on semiconductors and phosphors will be held in Germany at Garmisch-Partenkirchen during August 28–September 1. The introductory address will be given by Prof. W. Schottky, and some ninety papers will be read. Workers from a number of European countries and from Japan and the United States will be attending. Further information can be obtained from the organizing committee at Arcisstrasse 21, Munich 2.

The third Lignin Round Table will be held during September 24–26 at the Institute of Paper Chemistry, Appleton, Wisconsin, the subject being "The Biogenesis of Lignin". The meeting is sponsored jointly by the Committee on the Chemistry of Plant Products of the National Research Council and the Fundamental Research Committee of the Technical Association of the Pulp and Paper Industry. Further information can be obtained from Harry F. Lewis, Institute of Paper Chemistry, Appleton, Wisconsin.

An international conference on the fatigue of metals, organized by the Institution of Mechanical Engineers, will be held in London at the Institution's headquarters during September 10–14. Before the papers an address reviewing present knowledge on fatigue will be given by Dr. H. J. Gough, a past-president and honorary member of the Institution. The papers will cover the following fields: stress effects; effect of temperature and environment; metallurgical aspects; basic studies (mechanism, statistical theories and crack propagation); and the engineering and industrial significance of fatigue. Further information can be obtained from the Institution at 1 Birdcage Walk, Westminster, London, S.W.1.

The fourth of the national conferences on chemotherapy, organized by the Italian Society of Chemotherapy under the direction of Prof. Emilio Trabucchi (director of Pharmacological Institute, University of Milan), will be held in Rome at Palazzo Congressi all'E.U.R. during September 26–27, the subject being anti-tumoural chemotherapy. Afterwards, there will be a one-day symposium on actinomycin, which is being organized by Prof. S. A. Waksman, of Rutgers University, N.J. Further information can be obtained from the Secretary of the Italian Society of Chemotherapy, Pharmacological Institute, Via Andrea del Sarto 21, University of Milan.

The Second International Congress of Dietetics will be held in Rome during September 10–14 in the Palazzo dei Congressi dell' Esposizione Universale di Roma. The organization of the Congress is in the hands of the Italian Dietetic Association, which is also arranging an exhibition on food and food service equipment, to be held in conjunction with the Congress. The programme of the Congress is in four main sections: recent findings of nutritional research; methods of education in nutrition; principles and problems of feeding large numbers of people; and problems of training dietitians. All inquiries regarding the exhibition should be addressed to the Rassegna Internazionale di Alimentazione e Dietetica, S.A.I.C.A., via Giacinto Pullino 5, Rome. Further information on the Congress can be obtained from the Associazione Dietetica Italiana, via dei Penitenzieri 13, Rome.

The Institute of Biology is holding a symposium on "The Biology of Ageing" in the Anatomy Theatre, University College, London, during September 27–28. The papers to be given in the first session deal with ageing in bacteria, higher plants and animals. A second session will be devoted to physiological topics, followed by a series of papers on medical and sociological aspects of ageing in man. The final session will deal with psychological changes, the effects of nutrition and genetic variations in ageing. The symposium will, it is hoped, bring together biologists from differing disciplines to discuss a subject of common interest and will also provide a meeting ground for biologists, medical practitioners and sociologists. Further information can be obtained from the General Secretary, Institute of Biology, 41 Queen's Gate, London, S.W.7.

Erratum. In the communication entitled "A Method for following Lipolysis induced by Heparin", by Drs. G. Kubie, V. Felt and D. Reichl in *Nature* of July 28, p. 210, in each of the tables the phrase "*in vitro*" should read "intravenously".

NON-DESTRUCTIVE TESTING OF MATERIALS

THE summer meeting of the Non-Destructive Testing Group of the Institute of Physics was held this year in the University of Bristol during July 11–14, and the programme of the meeting was presented under the title of "Some New Aspects of Non-Destructive Testing". Dr. S. G. Hooker, director and chief engineer of Bristol Aero-Engines, Ltd., was the guest speaker at the introductory session, which was held during the evening of July 11. Dr. Hooker reviewed the many important problems of inspection which confront the aircraft manufacturer, and he showed that, in fulfilling the requirements of modern engineering development, existing inspection techniques are far from adequate. He made a plea for physicists to put every effort into the task of providing scientific information of a kind which will not only enable better use to be made of existing techniques but which will also make possible the development of new, and more suitable, inspection methods. By invitation of the Bristol Aeroplane Co., Ltd., a visit to the production plants of the Company, during the afternoon of July 13, formed a part of the programme of the meeting. Dr. Hooker said that the tour of his Company's works had been so arranged as to give emphasis to inspection procedure, and he hoped that the visit would add stimulus to the work with which the Non-Destructive Testing Group is concerned.

This was the first summer meeting of the Institute of Physics which has been devoted to what the Non-Destructive Testing Group decided to call "new aspects of non-destructive testing". The words "new aspects" were included in the title because, until now, it seems to have been the custom to regard non-destructive testing as concerned only with the detection of defects in engineering materials and components. This, of course, is not the case. The detection of defects forms but a part, albeit an important part, of the field covered by non-destructive testing, and a major aim of the meeting was that of directing the attention of physicists to the fact that the whole of physics is involved, in one way or another, in the scientific background of industrial inspection. If progress in the technology of inspection is to be maintained, considerable attention must be devoted to this background, and the right kind of scientific information must be made available to the technologists who fulfil the very important functions of developing inspection techniques and of putting these techniques into practice.

The interests of the Group are not confined to the application of physics in industry. During the past two years the application of physics in medical diagnosis has formed part of the Group's activities, and an evening discourse on "Physical Problems in Medical Diagnosis" was given, on July 12, by Prof. C. B. Allsopp (Department of Physics, Guy's Hospital Medical School, London). Prof. Allsopp showed, by referring to the work of his own Department, how this important application of the physics of non-destructive testing is put to good use by research workers in medical schools, and he aroused the interest of his audience by demonstrating the fact that an exchange of information between physicists engaged on industrial problems and physicists engaged on medical problems can be of mutual value. This was the first time an evening discourse had been included in the programme of a summer meeting of the Non-Destructive Testing Group, and Prof. Allsopp's lecture made it an outstanding event of the meeting.

In almost all the uses to which materials are put, their mechanical strength and mechanical behaviour are important factors—usually the most important factors—to be considered. Nearly all mechanical tests involve the destruction of the material under examination, so that if the mechanical behaviour of the actual material which goes into service is to be determined with the certainty required nowadays, then, in addition to the mechanical tests which are at present used, there is a need for a system of non-destructive testing which will provide an assessment of mechanical behaviour. The establishment of such a system presents a formidable problem; but present beliefs are that much success can be achieved by studying the influence of variations in the constitution and structure of materials on their mechanical and physical properties. If the changes brought about in these two types of property can be related empirically, then it will be possible to use those physical properties, which can be measured non-destructively, as a basis for the development of tests which will detect non-uniformity in the quality of complete batches of materials and will assess the significance of non-uniformity in terms of mechanical strength and mechanical behaviour.

Both Prof. W. Sucksmith (University of Sheffield) in his paper on magnetic properties and the structure of metals, and Dr. D. E. Thomas (Aluminium Laboratories, Ltd.) in his paper on the relationship between electrical resistivity and the mechanical properties of aluminium alloys, sounded a severe note of caution in this respect. Although magnetic and electromagnetic non-destructive testing instruments are already in use in industry for detecting non-uniformity in the quality of materials and components, Prof. Sucksmith and Dr. Thomas showed that indiscriminate use of any method of testing based on the detection of variations in either magnetic or electrical properties cannot, at this stage in our knowledge, be regarded as constituting a reliable inspection technique.

On the question of the assessment of the mechanical behaviour of materials the detection of fatigue in metals was chosen for discussion, and a complete session of the programme was devoted to it.

Dr. R. H. Hanstock (High Duty Alloys, Ltd.) described the fatigue process in metals and showed that the structural changes responsible for the formation of a fissure are highly localized. Physical properties, such as damping capacity, which provide a measure of the energy dissipated during a stress cycle, are an obvious choice for the detection of the onset of fatigue failure; but Dr. Hanstock produced evidence from his own work which showed that, whereas it is sometimes possible to obtain a rough estimate of the fatigue life of a material from initial values of hysteresis loss, in general, because of the localized nature of fatigue failure, insufficient change occurs in the overall energy dissipated per stress cycle for detection to be possible by existing methods of measurement.

Dr. N. Thompson (University of Bristol), reading a paper on structural changes and energy dissipation during fatigue, prepared by him and Dr. N. J. Wadsworth, described the work carried out at the H. H. Wills Physical Laboratory in which simultaneous observations were made of the metallographic changes visible on the surface, and of the changes in energy dissipation which take place during the fatiguing of copper, nickel and cadmium. From the results of this work Dr. Thompson showed that there is no direct connexion between the changes in energy dissipation and the progress towards fatigue failure.

The development of non-destructive inspection methods for non-metallic materials presents a difficult but, nevertheless, intensely interesting field of investigation for physicists. As in the case of metals, the promise of improved techniques is most likely to be found from studies made of the effects of structure on physical properties. Dr. P. T. Barrett (Terylene Council, Imperial Chemical Industries, Ltd.) reviewed the work which has been carried out on the development of tests for plastic fibres. In his paper on the testing of fibres and their molecular structure, he described the methods of physical measurement which provide information about the structure of fibres, and he discussed the mechanical properties of fibres in terms of their molecular structure.

It is one of the aims of the Non-Destructive Testing Group to encourage discussion on research investigations which have not necessarily been embarked upon for the purposes of non-destructive testing, but which are likely to produce results of use in the development of new non-destructive testing methods. In this connexion, four papers were presented at the meeting. Three of these described work in progress at the Atomic Energy Research Establishment, Harwell, and the fourth work which has been carried out at the National Physical Laboratory, Teddington.

Dr. L. E. Drain's paper on the principles and applications of nuclear magnetic resonance made an impressive contribution to the aims of the meeting. He enumerated twelve applications to which the measurements involved in his work could be put, and six of these applications were of direct use for the purposes of non-destructive testing. Mr. W. A. Runciman read a paper on optical fluorescence in non-destructive testing, in which he described the phenomenon of optical fluorescence and showed that, in addition to its use for detecting surface defects, it can be applied to problems of chemical and microscopic examination of materials. Mr. S. F. Pugh, in his paper on the effects of penetrating radiations on materials, reviewed present knowledge on radiation damage and indicated how the results of work in progress on this subject are likely to provide information on the structure of materials. Finally, Mr. M. F. Markham (National Physical Laboratory) gave a paper on the measurement of elastic constants by the ultrasonic pulse method. In this Mr. Markham described the propagation of stress pulses in æolotropic media, and the information he provided is not only of value from the point of view of establishing new techniques for the measurement of elastic constants, but also its application to the technology of ultrasonic inspection is of considerable importance.

The attendance at this meeting was one of the largest which the Non-Destructive Testing Group has had at its summer meetings, and it is the hope of the Group that the enthusiasm shown throughout the whole programme by those present is indicative of the fact that in the future there will be ample support given to the Group in its task of disseminating information on the physics of non-destructive testing.

E. G. Stanford

PLANT BREEDERS' CONFERENCE AT CAMBRIDGE

When the first conference of plant breeders was called by the Agricultural Research Council in 1947, forty workers met at the Plant Breeding Institute, Cambridge, then a research institute of the School of Agriculture, to discuss their common problems and to learn something of the work in progress there. In the intervening years the conference met annually until 1950 and biennially since then, inspecting work and discussing mutual problems ; the meetings have been held at the John Innes Horticultural Institution, first at Merton and later at Bayfordbury, at the Welsh and Scottish Plant Breeding Stations, and at the station at Loughgall of the Plant Breeding Division of the Ministry of Agriculture, Northern Ireland. With the seventh meeting held on July 4 and 5 at the Plant Breeding Institute, Cambridge, the initial cycle has been completed. The expansion of effort in plant breeding is indicated by the increase in the number of participants to 105 at this meeting, and by the fact that since the first meeting the four main plant breeding centres in Great Britain have been transferred to new stations to provide facilities adequate for the expansion that has occurred.

During the morning sessions, members of the staff of the Plant Breeding Institute gave short talks, which were followed by informal discussions. The afternoons were divided between tours of the field-plots and glasshouses, designed mainly to provide an indication of the scope of the work, and laboratory demonstrations and informal discussions between specialists to allow them to fill in the details of particular interest.

R. Riley gave an outline of the work on alien chromosome addition with reference to wheat breeding. Here the object has been to introduce new genes for particular desirable characters from primitive related species into wheat. From the results so far obtained in the production of new synthetic amphidiploids, the introduction of complete genotypes appears to bring in too many undesirable characters with the good. The work discussed concerns the addition to hexaploid wheat of single pairs of chromosomes from rye ; new plants with the addition to wheat of six of the seven rye chromosomes, both as disomics and as monosomics, were shown, as well as some in which only a part of a rye chromosome had been added. Initially the new forms tend to revert to the euploid condition, but it seems likely that balance may eventually be achieved.

K. F. Thompson discussed sporophytic incompatibility with special reference to the possibility of using a set of clones to produce commercial quantities of double-cross seed of uniform types of marrow stem kale. The interpretation of the data so far accumulated is complicated by the range of partial compatibility shown in some crosses, and by the finding that in other members of the family the degree of compatibility varies, probably with environmental differences.

In a survey of the outlook for herbage breeding, J. L. Fyfe stressed the advantages to the breeder of having clearly defined objectives to aim at in his work; a survey of the distribution and relative importance of the diseases of forage crops would facilitate the planning of the programme. He went on to discuss the general possibilities of new breeding methods based on the system used in the production of hybrid corn as compared with the older methods based on crossing and pedigree selection. Some degree of inbreeding can be of considerable value in any programme of breeding with crops which are normally cross-pollinated, even where the aim is not the exploitation of heterosis but only the production of a good variety. Inbreeding tends to provide new and otherwise inaccessible information about the material being studied; at the same time it may so reduce the genetic variability within the breeding lines that plot-size in trials can be reduced, with a consequent reduction in the cost of the trials. Once obtained, the inbred lines are available for use in strain building in the older systems, or after the newer techniques of the polycross or diallel crosses. In the discussion that followed, Dr. William Davies, director of the Grassland Research Institute, emphasized that the most important aspect of forage yield was not the absolute amount, but its distribution throughout the year—factors such as the influence of one cut upon the next and subsequent harvests must be taken into account. Other speakers mentioned difficulties in seed production; the cost may be materially affected by a character, such as stiffness of straw, having little relevance to the vegetative production of a crop.

Miss J. M. Drayner gave an account of observations on the breeding system and heterosis in field beans. Both selfing and crossing occur in the crop, and a balance is maintained because the hybrids tend to be self-pollinated and the inbreds tend to cross. Marked heterosis can be seen in hybrids between third-generation inbreds. It may be possible to produce high-yielding stocks by utilizing the tendency of inbreds to cross, coupled with the use of male sterility, recently discovered in the breeding material.

G. E. Russell discussed virus strain relationships in connexion with the virus yellows problem in sugar beet. Because there has so far been no indication that any form of immunity or resistance to this disease may exist, the work is at present concentrated on the search for tolerance to the disease. To cover a wide field as rapidly as possible, a severe necrotic strain of the virus is being used for the routine inoculations, because it normally produces distinct and severe symptoms in a few days. Although this strain is a convenient one for use in the screening tests, the proper orientation of the breeding programme must depend on a better knowledge of the distribution and importance of the strains in the field. Dr. A. R. Trim spoke of his work on the nucleic acids of sugar beet, both in relation to genetic problems and in connexion with the problems of virus yellows. The indications are that the virus may be a ribonucleoprotein, but analysis of nucleic acids recovered from beet has not progressed far enough to provide definite evidence for this.

Selection for yield in breeding cereals was discussed by F. G. H. Lupton, who paid particular attention to modifications in the method of pedigree selection and to the improvement of techniques in yield trials. Wheat hybrids from a wide range of parent varieties are now being handled at the Plant Breeding Institute, and to speed up the work selection in the F_2 and F_3 generations is made by eye; but from the F_4 generation onward bulks of families are included in yield trials, with only a small proportion of sub-cultures retained for multiplication. Some of the newer trial lay-outs have given improved precision, but the analysis of others is so tedious that alternative methods of comparison are being tried. Other detailed discussion included questions of plot-size and shape, and the effects of guard rows and their omission.

The problem of choice of parental combinations was mentioned by Lupton and taken a stage further by R. N. H. Whitehouse, who described a first attempt at the analysis of diallel crosses in order to assess the comparative value of four wheat varieties, differing in various characters, as parents for the production of new hybrids. He suggested that plant breeders may find the method of value in dealing with other crops.

H. W. Howard gave an account of his investigation of a potato chimera, similar to the variety Red King, that arose in a stock of the variety King Edward. In breeding behaviour the new potato resembles King Edward, indicating that only the outer layer of the apical meristem is involved in the change. In using Asseyeva's technique of eye removal to stimulate the production of adventitious buds in the lower tissues, some plants with white-skinned tubers were produced, as well as plants with tubers of the King Edward type, white splashed with pink. The mechanism of the 'mutation' for the origin of the white type remains in doubt, particularly because such types are also produced when tubers from a seedling with a splashed tuber are subjected to the Asseyeva technique.

Work demonstrated in the field and laboratory included the breeding of new winter and spring wheats with good field-characters; selection techniques have been improved by the introduction of controlled tests of resistance to rust and eye spot, and by the use of special equipment for small-scale milling and dough testing. In the improvement of barleys, yield, strength of straw, and resistance to mildew are among the desired characters in the field; to aid selection in the laboratory, routine nitrogen determinations are made and a micro-malting test has been introduced. Improvement of hardiness of winter types and resistance to frit fly in spring types are among the main points in the work on oats, where quality is being assessed by laboratory determinations of oil content and husk percentage. In the work on the cytogenetics of the Triticinae, the addition of rye chromosomes to wheat was demonstrated, and a number of synthetic amphidiploids were also shown.

An outline was given of the work on beans and clover, where the main emphasis has been on yield and resistance to pests and diseases. In lucerne the main problems concern breeding techniques and seed production; but here, as with timothy and cocksfoot, there is the important question of achieving a balance in seasonal production in the drier parts of Britain. In marrow stem kale, uniform inbred lines differing in habit were shown; hardiness and quality are being studied in this crop. Work on potatoes has recently been extended to include resistance to eelworm in addition to the work on blight and the study of cooking quality. In sugar beet selection for resistance to bolting and the search for tolerance to virus yellows were shown.

PEST INFESTATION RESEARCH

THE greater part of the report for 1955 on "Pest Infestation Research"* is devoted to the collected summaries of some ninety investigations in progress at the Department of Scientific and Industrial Research Pest Infestation Laboratory at Slough during 1955. Many of these investigations were continued from earlier years, and among those reaching completion last year was the detailed study of the behaviour of the carpet beetle. The complex life-cycle of this insect, which involves the deposition of eggs in birds' nests in the eaves of houses, is described and correlated with the mode of infestation. Other biological problems studied include the elucidation of the life-histories and physical limits of several species of beetles and mites which are important pests of foodstuffs.

Problems associated with the bulk storage of various types of grain formed a prominent part of the Laboratory's work. Field experiments on the use of underground grain-storage pits, originally started in Africa, were continued at Slough. The success of this method was found to be due to the rapid decrease in the oxygen concentration, which led to the death of the infesting insects.

Much of the work of the Insecticide Section is of immediate practical importance, being concerned with such problems as the insect penetration of multi-ply paper sacs, the toxicity of malathion to insects, the control of the cacao moth in warehouses and the assessment of spraying and dusting equipment. A major item in this Section's programme of work was an investigation on the means of controlling insect damage to stored groundnuts in Gambia. The chief damage was caused by the groundnut beetle (*Coryedon fuscus*), which attacks the surface layers in the piles of bulk-stored nuts, where up to 94·5 per cent damage was reported after four months storage. Several experimental trials were initiated and a satisfactory degree of control was achieved using insecticidal dusts. Attempts to protect shelled nuts by using bags of various materials did not prove so successful.

The biochemical work of the Pest Infestation Laboratory was largely concerned with studies on the chemical reactions of insecticides with foodstuffs and with fundamental research into the mode of action of insecticides. A particular example of the latter is the investigation on the effects of DDT on phosphorus metabolism in insects, which is likely to prove a valuable addition to our knowledge of the mechanism of insecticidal poisoning in insects. As the report points out, insect biochemistry remains a relatively unexplored field and much research on the normal insect is required before the biochemical effects of insecticidal action can be properly appreciated. It is gratifying to read, therefore, that a proportion of the biochemical work at Slough falls into this category.

An interesting development announced in the report is the proposal to form a pool of entomologists and chemists. The members of the pool will be attached to the Laboratory at Slough and will be available to visit the Colonial territories to undertake specific investigations as the need for them arises. This policy is of obvious importance to Great Britain in view of the large imports of raw foodstuffs, and it is clearly desirable to be able to control infestation at the source. Colonial liaison is, however, not a recent departure, for it has long been an important part of the work of the Pest Infestation Laboratory. During 1955 several investigations were in progress in various Colonial territories, and a great deal of the work done at Slough was directed towards solving problems of food storage in the Colonies.

VISUAL DEMONSTRATION OF ALLELIC DIFFERENCES WITHIN CELL NUCLEI

By PROF. H. G. CALLAN and L. LLOYD
Department of Natural History, The University, St. Andrews

THE characteristic patterns of cross-banding on the salivary gland chromosomes of dipteran larvæ have been shown beyond reasonable doubt to reflect the linear genetic differentiation of these chromosomes. Some of the strongest evidence in favour of this view comes from the cytological study of chromosomes which, as a result of genetical experiment, have been supposed to possess gene arrangements differing from a standard sequence by inversion, translocation, duplication or deletion. Some of these structural rearrangements are associated with clear-cut phenotypic effects: of these, the 'Bar' mutants of *Drosophila melanogaster*[1] were the first to be so recognized.

The great majority of *Drosophila* mutants cannot, however, be differentiated from wild-type flies when the salivary gland chromosomes of mutant and wild-type are compared. This is certainly not due to inadequate techniques or insufficiently painstaking studies: often enough the chromosome region in which a particular mutant gene is located has been very precisely known.

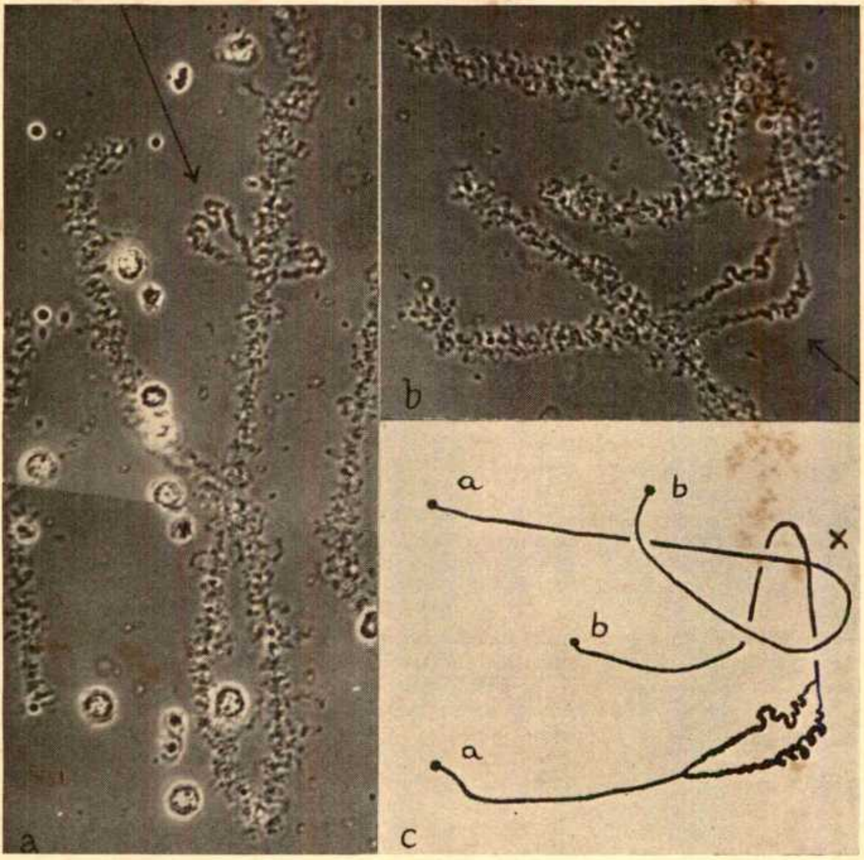

Fig. 1

(*a*) Phase-contrast photograph (× 375) of bivalent X of *T. c. carnifex*, individual *E*. The large loop-pair marked with an arrow on one chromosome is absent from the partner chromosome. The homologous free chromosome arms appear to be of unequal length, but this is merely due to fore-shortening

(*b*) Phase-contrast photograph (× 375) of bivalent X from another oocyte from the same newt. The chromomere from which the large loop-pair originated has suffered breakage transverse to the chromosome axis, in the way very characteristic of lampbrush chromosomes, so that the large loops, marked with an arrow, form a double connecting bridge over the axial break. These large loops are again absent from the partner chromosome

(*c*) Schematic diagram of the bivalent shown in (*b*). Homologous arms are marked *a*, *a*, and *b*, *b*, while the single point of association between homologues is marked *x*

The lampbrush chromosomes of amphibian and other oocyte nuclei also show linear differentiation. This differentiation is most clearly to be seen in the diverse morphologies of the pairs of loops arising from chromomeres in the chromosome axes. There is strong circumstantial evidence that each loop consists of a reflected fibre originating from a chromomere. Around this fibre the primary products of gene activity accumulate (and from which they disperse into the nuclear sap in various forms), the nature and rates of synthesis and of dispersal of the accumulated products determining loop morphology[2]. By studying the distribution of loops of characteristic morphology we have been able to identify each of the twelve bivalent lampbrush chromosomes of the newt *Triturus cristatus carnifex*. We have not attempted to construct comprehensive maps of any of these chromosomes: this would indeed be a very difficult task in view of the varying morphologies of these chromosomes at different stages in the growth of the oocytes. We have instead paid particular attention to the most conspicuous and characteristic loop structures and have so far deliberately concentrated our attention on oocytes of a limited size-range.

In nuclei from oocytes of a given size taken from an individual newt's ovary, homologous chromosomes may be morphologically identical (at least to the extent that we have not noticed differences between them) or they may be clearly non-identical. The non-identity may consist in the presence of a conspicuous pair of loops at a particular locus on one homologue and the absence of comparable loops on the partner chromosome. A typical example of this condition is shown in the accompanying phase-contrast photographs (Fig. 1) of bivalent X (tenth longest, bivalent I being the longest) of *T. c. carnifex*, individual *E*. Inter-homologue differences such as the one illustrated characterize individual newts and are constant from oocyte to oocyte. Individual newts differ from one another in respect of these inter-homologue differences. We have paid careful attention to this matter in five specimens of *T. c. carnifex*, and each of these newts is recognizably distinct. Bivalent I is heteromorphic in all five specimens, though the loci at which it is heteromorphic differ from one individual to another. Bivalent X is heteromorphic in two of the five individuals and bivalent XII is heteromorphic in one. Although the other bivalents appear superficially to be homomorphic, we have little doubt that consistent differences between homologues would also be noticed in these if the cytological study were sufficiently thorough.

The condition described above cannot be due to structural rearrangements of gene sequence by inversion, duplication or translocation such as can be recognized so readily in the salivary gland chromosomes of Diptera: loops of highly characteristic morphology may be found at one chromosome locus in one of two partner chromosomes and nowhere else within the entire complement. Deletions might account for the absence of a particular loop at a given locus; but if this explanation of the phenomenon is to be accepted, four specimens of *T. c. carnifex* must be deletion homozygotes for a locus on bivalent XII which in the fifth specimen regularly bears a pair of conspicuous spherical objects on one homologue, these being equally regularly absent from its partner.

We suggest an alternative explanation: that non-identity of loop pairs at homologous chromosome loci is a direct expression of genetic heterozygosity at these loci, that is, that different alleles of a given gene may produce loops of differing morphology. As mentioned earlier, differences of loop morphology in all probability depend on differences in the nature or rate of synthesis or of dispersal of the accumulated primary products of gene activity. If this explanation be accepted, then why should allelic differences be visible in lampbrush chromosomes but not in *Drosophila* salivary gland chromosomes? There is evidence, both from studies on salivary gland chromosomes[3] and on lampbrush chromosomes, that genes in a physiologically active state take the form of extended fibres: compact chromomeres which are not spun out into fibres may represent genes in a state of inactivity. The chromomeres of salivary gland chromosomes are for the most part compact, whereas those of lampbrush chromosomes during the active growth phase of oocytes are for the most part extended into the fibre cores of the lateral loops. Thus allelic differences in salivary gland chromosomes are only likely to be detectable if they concern genes which are physiologically active in salivary gland nuclei; for example, loci involved in nucleolus- and Balbiani-ring formation: and Beermann[3,4] has demonstrated what are probably allelic differences at precisely such loci in the salivary gland chromosomes of chironomids. In oocyte nuclei, on the other hand, where the great majority of the genes may be adjudged to be physiologically active, we may reasonably expect allelic differences to be generally discernible. MUTATIONS IN *DROSOPHILA MELANOGASTER* GROWN ON MEDIA CONTAINING CARBON-14-LABELLED SUGARS

By Prof. E. SUOMALAINEN
University, Helsinki

Prof. O. TURPEINEN
College of Veterinary Medicine, Helsinki

AND

Prof. R. NIINI
University, Helsinki

SINCE Muller in 1927 and Stadler in 1928 published their classical studies on the strong mutagenic action of X-rays, high-energy radiation has been the foremost means of inducing mutations experimentally. At first only external irradiation was used; but in recent years the mutagenic action of radioactive materials absorbed by the cells has also been studied. These investigations, reviewed by Muller[1], have dealt with the mutagenic action of radioactive phosphorus and sulphur. Especially interesting is the question whether the transmutation of a radioactive atom located at a strategic point within a gene would result in the mutation of this gene. Although it has been difficult to decide whether the observed mutagenic action was entirely caused by the released beta-radiation or in part also by the transmutation of radioactive atoms located in the chromosomes, certain experiments dealing with the effects of radioactive phosphorus on *Drosophila* have shown that at least under the conditions used the mutations were induced at a rate which could be approximately accounted for by the released beta-radiation alone[2-4]. Thus King found that the radiation from internally located phosphorus-32 atoms was mutagenically effective, but that in the case of male *Drosophila* fed upon phosphorus-32 as adults for 24 hr. there was no indication that internal phosphorus-32 were mutagenically more efficient than external phosphorus-32.

In the experiments to be reported here the mutagenic action of carbon-14 was investigated by rearing *Drosophila melanogaster* individuals from eggs to adults on media containing carbon-14-labelled sugars.

The medium used was a modification of Spencer's[5] medium and was prepared as follows. 2 gm. of powdered agar were added to 320 ml. of water, and the mixture brought to boiling point. 15 ml. of living brewer's yeast were stirred in, and the mixture was boiled for 15 min. 40 ml. of syrup were added. 40 ml. of semolina were thoroughly mixed with 40 ml. of water. This was stirred into the hot medium, and the mixture was brought to boiling point. Then 1·6 gm. of dry 'Bonomold *OM*' (AB Bofors Nobelkrut, Sweden) were added and thoroughly stirred in, after which the medium was boiled for 10 min. Then a small amount of solution containing carbon-14-labelled sugars was added and after thorough mixing the medium was immediately poured into culture bottles, each of which received about 50 ml. of medium.

The carbon-14-labelled sugars were prepared photosynthetically by means of *Canna indica* leaves. Hassid's[6] procedure was mainly followed. After photosynthesis the leaves were extracted with 80 per cent ethanol, the extract was concentrated on the steam-bath, and water was added. Lipids, pigments, and other materials were removed by treating the aqueous residue with ether in a Kutscher–Steudel extraction apparatus. A small quantity of glucose was added as carrier to the aqueous solution, which then was evaporated to dryness under vacuum.

The radioactive sugars were added to the culture media at two levels of activity, namely, approximately 1 millicurie and 0·1 millicurie per culture bottle.

The culture bottles were kept in an incubator at 23–24° C. Cultures with the same medium from which radioactive sugars had been omitted served as controls. Three *Drosophila melanogaster* pairs were introduced into each culture bottle. They were of the young wild-type individuals of Oregon-*K* stock. The new generation developed in fifteen days.

The males grown from eggs to adults on the media containing radioactive sugars as well as the control males were tested for the presence of the X-chromosome lethals by means of the Muller-5 technique (cf. Demerec[7]). In the experiments, F_1 females from the crosses between one Muller-5 female and one treated male (these F_1 females were offspring of several treated males) were individually mated, each with one Muller-5 male. The presence of the X-chromosome lethals was determined according to the criteria presented by Demerec[7].

The results are shown in Table 1.

Table 1. THE PRESENCE OF X-CHROMOSOME LETHALS IN THE FIRST GENERATION REARED ON THE MEDIA CONTAINING CARBON-14-LABELLED SUGARS

^{14}C activity of medium per culture bottle	F_1 females tested	F_1 females with offspring	Free from X-lethals	X-lethals No.	X-lethals per cent
1 mc.	202	180	175	5	2·8
0·1 mc.	152	139	138	1	0·72
None	90	82	82	0	0

The experiment was continued by placing the flies reared from eggs to adults on the media containing carbon-14-labelled sugars into new culture bottles containing the same media, either radioactive media of two different levels of activity or a non-radioactive control medium. Three pairs of flies were introduced into each bottle. Their male offspring, which thus represented the second successive generation reared on the carbon-14-labelled media, were tested for the presence of the X-chromosome lethals.

The results are shown in Table 2.

Table 2. THE PRESENCE OF X-CHROMOSOME LETHALS IN THE SECOND GENERATION REARED ON THE MEDIA CONTAINING CARBON-14-LABELLED SUGARS

^{14}C activity of medium per culture bottle	F_1 females tested	F_1 females with offspring	Free from X-lethals	X-lethals No.	X-lethals per cent
1 mc.	209	183	179	4	2·2
0·1 mc.	163	149	148	1	0·67
None	80	69	69	0	0

To assess the activity of the media and of the flies, samples of both were taken at the end of the experiments. These samples were dried and oxidized with the Van Slyke–Folch[8] mixture. The liberated carbon dioxide was absorbed into barium hydroxide solution and the barium carbonate precipitate formed was collected on a filter paper disk. After drying, its activity was measured by means of a thin end-window Geiger–Müller counter. The counts were converted into absolute counts by comparing them with counts obtained from a calibrated barium carbonate standard (from Tracerlab, Boston, Mass.) under the same counting conditions. The results of the activity determinations are shown in Table 3.

Table 3. THE ACTIVITY OF THE MEDIA CONTAINING CARBON-14-LABELLED SUGARS AND OF THE FLIES REARED ON THESE MEDIA

	Specific activity (absolute) per mgm. of carbon	
	disintegrations/sec.	microcuries
First generation		
0·1-millicurie medium		
Medium	909	0·0246
Flies	971	0·0262
1-millicurie medium		
Medium	9,628	0·260
Flies	9,601	0·259
Second generation		
0·1-millicurie medium		
Medium	893	0·0241
Flies	904	0·0244
1-millicurie medium		
Medium	9,801	0·265
Flies	10,081	0·272

For the purpose of computing the radiation dose received by the flies during their development from eggs to adults under those experimental conditions, we note that the average activities of the media were 0·263 and 0·0244 microcuries per mgm. of carbon, respectively. Since it was calculated that the media contained 73 mgm. of carbon per gm., the activities of the media were 19·2 and 1·78 microcuries per gm. Taking 0·05 MeV. as the value for the mean energy of the carbon-14 beta-particle, we find that the amounts of energy liberated in these media were 4,920 and 456 ergs per gm. in 24 hr., which would be equivalent to 53 and 4·9 r. in 24 hr., respectively. Thus, if the carbon concentrations in the flies were the same as that of the medium, the flies during their 15-day period of development had received a total radiation dose of about 800 r. on the '1-millicurie medium' and of about 75 r. on the '0·1-millicurie medium'. Actually, the carbon concentration must have been somewhat higher in the flies and, consequently, the radiation dose also larger, perhaps by some 50 per cent.

The frequencies of the X-chromosome lethal mutations were very similar in both series of experiments. The numbers of mutations observed in flies reared on the '0·1-millicurie medium' are not significantly different from zero. On the other hand, the numbers of mutations on the '1-millicurie medium' are statistically significant if the results of both experiments are pooled ($\chi^2 = 3{\cdot}83$, degrees of freedom 1, $P = 0{\cdot}05$). Thus we feel justified in concluding that the incorporation of radioactive carbon-14 into the medium and through it also into the flies increases the frequency of mutations.

As described above, the total radiation dose which the flies received during their 15-day period of development on the '1-millicurie medium', was about 800 r. The frequency of the X-chromosome lethals observed in our experiments, 2·2–2·8 per cent, is approximately the same as those found by several investigators after a dose of 1,000 r.[9–13]. In most of these experiments little attention has been paid to the age of the irradiated flies, which has been shown to influence considerably the number of mutations[13,14]. This remark also applies to our own experiments, in which, however, the *Drosophila* flies received irradiation at the same dosage during their whole period of development. The above comparison indicates that the increase in the number of mutations observed in our experiments can be accounted for, at least mainly, by the mutagenic action of released beta-radiation. This comparison, however, cannot be perhaps considered quite exact, since the irradiation in our experiment, in contrast to all the above-mentioned studies, was distributed over the whole period of development.

Biochemical Evolution : Position of the Tunicates

THE biochemical differentiation[1] between the vertebrates and the invertebrates rested upon the finding that phosphocreatine and phosphoarginine were characteristic of these two classes respectively. Recently, the discovery of phosphagens other than phosphoarginine in invertebrates has suggested some modification of this generalization; but there are no reports in the literature suggesting the presence of a phosphagen other than phosphocreatine in the vertebrates.

The work[2,3] on members of the intermediate group of protochordates, which indicated the presence of phosphoarginine in the atrial muscle of tunicates, created an anomalous situation, inasmuch as the tunicates appeared to reverse the general chordate pattern[4] biochemically characterized by the presence of phosphocreatine.

In connexion with investigations on creatine phosphokinase[5] and arginine phosphokinase (unpublished results), the opportunity occurred to examine two tunicates, *Pyura* sp. and *Pyura stolonifera* (Heller), for the presence of arginine phosphokinase and phosphoarginine. The atrial muscles were removed immediately after collection (from the south coast of New South Wales) and frozen in liquid nitrogen to prevent decomposition of the phosphagen. A portion of this frozen material was extracted in the cold with trichloroacetic acid (10 per cent) and the extracts neutralized after filtration. A water-soluble ethanol-insoluble fraction of barium salts was obtained which contained a phosphorus compound unstable in 0·1 N hydrochloric acid at 60°. The compound was identified as phosphocreatine by ascending paper chromatography in a number of solvent systems. The compound, moreover, did not react with adenosine diphosphate in the presence of arginine phosphokinase isolated from crayfish muscle, but did react with it in the presence of creatine phosphokinase from rabbit muscle.

Another portion of the muscle was extracted with boiling water, and from the filtered extracts, after treatment with ion-exchange resins, a picrate was obtained which possessed a melting point identical with creatine picrate. Chromatography of the initial extract in six solvent systems revealed only one spot reacting with α-naphthol and diacetyl and corresponding in position with authentic creatine. This spot did not give a Sakaguchi reaction, nor did it react with ninhydrin. The guanidine was phosphorylated by creatine phosphokinase but not by arginine phosphokinase.

A third portion of the frozen muscle was finely ground and extracted with 1·5 vol. of water in the cold room for 18 hr. After centrifugation, the extract was treated with ammonium sulphate and a protein fraction obtained which showed creatine phosphokinase activity. No trace of arginine phosphokinase activity was detected in either the crude or partially purified extracts. The enzyme was active not only with authentic phosphocreatine and creatine as substrates, but also with the free base and its phosphorylated derivative isolated from the muscle.

The generalization of Needham *et al.*[3] (that the tunicates contain phosphoarginine) is based on equivocal chemical evidence gained from an investigation of one species but has been generally accepted[4,6]. The present results indicate the absence of arginine, phosphoarginine and arginine phosphokinase in the tunicates as represented by two species. On the other hand, they prove conclusively the presence of creatine, phosphocreatine and an enzyme possessing creatine phosphokinase activity.

Though it is perhaps not permissible to conclude that the tunicates as a class possess creatine, etc., the present work is consistent with, and provides biochemical support for, the accepted phylogenetic classification of the tunicates and therefore removes the anomaly referred to by Wald[4].

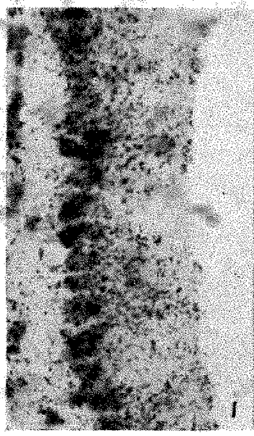
Effect of X-Rays on the Metabolism of Cell Nuclei of Non-dividing Tissues

ADULT mice were given single intraperitoneal injections of either a solution containing ^{35}S-DL-methionine or [8-^{14}C]adenine. Some of the animals were given whole-body irradiation immediately before injection. The animals were killed at various times after injection, and organs fixed for 1 hr. in acetic acid–alcohol (1 : 3) followed by formol saline; autoradiographs were prepared by the stripping film technique. The methods employed have been described previously[1].

After injection of labelled methionine some tissues with extremely low mitotic indexes, such as thyroid, seminal vesicle, tracheal epithelium, nerve cells and epididymis, give nuclear autoradiographs suggesting protein metabolism. Although nucleus and cytoplasm are labelled, the resolving power of the method is undoubtedly sufficient to localize sulphur-35 in parts of the cells. Only some of the nuclei are positive in those tissues, the proportion varying within wide limits.

The effect of X-rays on nuclear protein metabolism in the columnar epithelium in the trachea 4 hr. after irradiation and injection is shown in Figs. 1 and 2; numerical values are given in Table 1. Weakly positive nuclei were scored as negative, since the photographic grains above them might have been due to sulphur-35 in adjacent cytoplasm. The strength of the autoradiograph above the cytoplasm of the epithelial cells in the trachea is not markedly affected by the irradiation (cf. Figs. 1 and 2). It is about equal to that in positive nuclei in animals killed four hours after injection. Two hours after injection the concentration of sulphur-35 is higher in the cytoplasm of all cells than in positive nuclei. Fewer



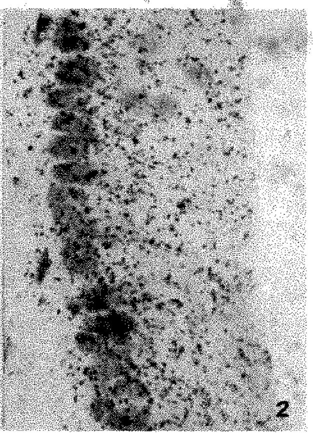


Fig. 1. Stripping-film autoradiograph of the tracheal epithelium of a mouse 4 hr. after injection of ^{35}S-DL-methionine. No irradiation. Hæmatoxylin and eosin stain after photographic processing

Fig. 2. As Fig. 1, but 1,000 r. X-rays before injection

positive nuclei are observed 16 and 24 hr. after injection, but marked accumulations of sulphur-35 are noticeable in the cytoplasm surrounding the nuclei. The secretion is labelled. Table 2 summarizes the changes in the strength of autoradiograph.

No cells in division were seen in the tracheal epithelium in sections stained by the Feulgen reaction, whereas a number of mitoses was observed in the strongly labelled squamous epithelium of the œsophagus of unirradiated animals; mitosis, therefore, is not influenced by the injected radioactive material. It can be concluded that neither the observed nuclear uptake of labelled methionine nor the effect of X-rays on this incorporation is connected with mitosis.

Twenty-four to seventy-two hours after injection of [8-^{14}C]-adenine, a nuclear autoradiograph indicating nucleic acid metabolism was observed in the seminal vesicle and tracheal epithelium in slides treated with ribonuclease before applying the film. Staining with methyl-green pyronine shows that the ribonuclease had hydrolysed the ribose nucleic acid in the nuclei in the preparation.

The connexion between amounts of the nucleic acids and protein metabolism was first pointed out by Brachet[2] and Caspersson[3]. Recently, Gale[4] and Mirsky[5] have shown that the incorporation of amino-acids into cell suspensions derived from dividing cells depends on the presence of intact nucleic acid.

Table 1. EFFECT OF X-RAYS ON NUCLEAR PROTEIN METABOLISM IN THE TRACHEAL EPITHELIUM

Dose (r.)	No. of animals	Percentage positive nuclei	
		Single animals	Mean
0	4	77, 66, 69, 55	67
200	1	31	31
1,000	3	20, 17, 24	20

The percentages are based on counts of 300–400 cells per animal.

Table 2. CHANGES IN THE STRENGTH OF AUTORADIOGRAPH IN THE TRACHEAL EPITHELIUM AFTER INJECTION OF ^{35}S-DL-METHIONINE

Time after injection of methionine	Cytoplasm	Perinuclear	Positive nuclei	Secretion
2 hr.	++	−	+	+
4 hr.	++	−	++	+
16 hr.	++	+++	+→++	++
1 day	++	+++	+→++	++
2 days	+	++→+++	+	+
8 days	+	+	+*	+

−, Negative; +, ++, +++, strength of autoradiograph as estimated. These values are not based on grain counts.
*Very few positive nuclei.

Preliminary results on other tissues show significant differences in the incorporation of methionine as well as the connexion indicated with nucleic acid metabolism as shown by incorporation of [8-^{14}C]-adenine, and the findings reported here cannot be taken to be of general validity for all tissues showing signs of nuclear protein metabolism. It is more likely, judging from preliminary observations, that the various differentiated tissues show combinations of nucleic acid and protein metabolism peculiar to themselves.

I wish to thank Dr. A. Glücksmann and Dr. N. B. Myant for much helpful discussion.

Mutagenic Effect of Thermal Neutrons on Wet and Dry Tomato Seed

SEEDS of two different lots (line 208 and line 215) of the same autodiploid *L. pimpinellifolium* were exposed to thermal neutrons in the reactor at Brookhaven National Laboratory in February 1955. Part of the seed was exposed dry (about 8 per cent moisture) and another part exposed wet (soaked 24 hr. at 25° C. and then sealed in plastic bags at 3° C. for irradiation). Wet seeds were saturated with water and, except for the 24-hr. soaking period and the period of irradiation exposure, were kept at 3° C. until dry again.

In treating line 208, three different wet pretreatments were used: 0·2 per cent colchicine, 0·2 per cent paradichlorobenzene, and distilled water. However, most of the results were homogeneous among the three pretreatments so they have been grouped and reported together as a single wet treatment. One item, mean days to germinate, did vary among the wet pretreatments, seed treated with paradichlorobenzene requiring about 1·5 days longer to germinate.

The principal results from the line 208 experiment are given in Table 1. Germination, survival and sterility data are comparable for both wet and dry seeds, except for the slower germination of wet-treated seeds, which is entirely due to the delay, noted above, associated with the paradichlorobenzene subtreatment.

Mutation data were taken by selfing R_1 plants and observing 36–72 seedling progeny from each R_1 plant for lethal and visible mutations. Lethals were expressed as a 25 per cent reduction in germination and visibles as 25 per cent of the progeny. Visibles were classified as 'chlorotic lethals', 'morphological lethals', 'chlorotics' and 'morphologicals'. The results, given in the last column of Table 1, indicate a much higher

Pretreatment	Thermal neutron dose (10^{13}/cm.^{2})	No. planted	Per cent germ.	Mean days to germ.	Per cent survival	Per cent plants sterile	No. tested for mutation	Per cent having seedling mutation
Control	0	648	97	5·77	100	0	51	0·0
Wet and dry								
Dry	11·00	72	93	7·24	100	72	18	38·9
Wet	11·00	576	76	7·40	87	53	75	54·7

mutation-rate for dry-treated seed than for wet-treated seed, although these differences are in no way indicated in the foregoing germination, survival and sterility data from R_1 plants.

Line 215, which is genetically identical to line 208, was used in a different experiment performed at the same time but involving a different series of wet treatments and only one irradiation exposure of 11·00 × 10^{13} thermal neutrons/cm.^{2}. Wet treatments included water and equimolar solutions of the iron, calcium and potassium chlorides, nitrates and sulphates. Since some of these salts produced response differences, the 'wet' results given in Table 2 are summations from only those treatments that were not dissimilar from distilled water.

It is evident in these results (Table 2) that tomato seeds will withstand extremely high doses of thermal neutrons. Barley seed, which is roughly typical of most other seed in this respect, fails to produce plants[1] after about 1·9 × 10^{13} thermal neutrons/cm.^{2}. Line 215 tomato seed, however, produces functional plants, almost half of which are fertile, after an exposure that is five times greater than the lethal dose for barley. Furthermore, mutation-rate, which in barley at the top dose[1] of 1·4 × 10^{13} is about 13 per cent, is about 55 per cent in line 215 at dose 11·0 × 10^{13}. This strongly suggests that the functional resistance enjoyed by tomato seeds is cytoplasmic in origin and that genetic damage increases as an approximately linear function of dose in spite of somatic protection.

The difference in sensitivity of two lots of genetically identical seed (lines 208 and 215), which is shown by comparison of the 11·00 × 10^{13}/cm.^{2} treatments in Tables 1 and 2, is characteristic of tomato results, sensitivity differences depending mostly on non-genetic factors.

With regard to the effect of hydration on response to thermal neutron irradiation, the results from wet and dry treatments show a striking similarity. Wet- and dry-treated seeds (Tables 1 and 2) germinate about as well and about as rapidly, and the plants survive about as well. However, there is a suggestion in both sets of results that plants from wet-treated seeds at high doses are less likely to be sterile and, at lower doses (Table 1), are less likely to have a recessive seedling mutation. Whether this amounts to a real genetic protection by hydration remains to be determined; but, at least, it seems evident that hydration does not increase either somatic or genetic sensitivity of these seeds. Ehrenberg *et al.*[2] have X-ray data, somewhat comparable to these, for mutagenic sensitivity of pre-soaked and dormant barley seed. They show that, at low doses, water increases the genetic effect but, at higher doses (about 15,000 r.), mutation-rate in presoaked seed is "often lower than in dormant seeds". Our results from thermal neutron irradiations at much higher levels than those of Ehrenberg indicate that the genetic protection by water, which began to appear at his high doses, may actually exist. Such protection, however, cannot yet be construed to indicate genetic protection on a cellular level, because the relationship between mutations induced and mutations recovered is still not established in plants.

This work was aided by contract *AT*(11-1)–335, Atomic Energy Commission. I wish to acknowledge facilities made available in the Biology Department, Brookhaven National Laboratory, where the seed treatments were carried out. The technical assistance of Miss Isobel Allan and Mrs. Mary Roser has been invaluable.

Adsorption of Red-Cell Components by Siliceous Earths

IN a recent paper by Lovelock[1], the hæmolysis of suspensions of washed human red cells by alumina has been described. The conclusion is drawn from this work that alumina adsorbs dissolved lipids, derived from the erythrocyte membrane, thus hastening the process whereby lipids pass from the cell membrane into (aqueous) solution, leading to the breakdown of the cell.

Prior to my knowledge of this work, I had investigated an accidentally observed phenomenon, the hæmolysis of human red cells by suspensions of a diatomaceous-earth filter-aid, 'Hyflo Super-Cel'[2], used in chromatography. It was possible to show the adsorption of quite large amounts of lipid material on to the powder after mixing with red cells for a few minutes. Extraction of the recovered powder was performed with chloroform/methyl alcohol mixtures, and the extracts analysed for cholesterol, phospholipid and nitrogen. Control experiments in which the powder was shaken with 0·15 M sodium chloride solution used for washing the cells prior to treatment yielded negligible values for the various substances. In two experiments of the type described, alumina was used for comparison.

In addition, some of the lipid material, after extraction from the powder, was freed from cholesterol and dissolved in a mixture of 10 per cent *iso*-propyl alcohol in benzene. Small quantities of this were used for making spread-films on water; the ability of suspensions of 'Hyflo Super-Cel' to lower the surface pressure of these films was measured with a Langmuir film balance. It was found that, while simply introducing a suspension of the powder into the water below the powder had no effect, directing a stream of the particles upwards towards the underside of the film lowered the surface pressure rapidly and considerably.

The results of this work suggest that, at any rate in the case of the siliceous material used, hæmolysis results from an interaction between the cell surface and the powder particle, with direct adsorption of components of the membrane. Particle-size appears to be an important factor in this process.

Details of this work have been submitted for publication elsewhere, and further quantitative investigations of the factors controlling interaction between cell surfaces and solid adsorbents is proceeding.

Induced Change from Culture Form to Blood-stream Form in *Trypanosoma mega*

In its vertebrate host, a trypanosome multiplies in the trypanosoma form while, in its invertebrate host, it first takes the crithidial form, which is no longer infective, to reappear as metacyclic forms at the end of its cycle. Similarly, in culture, the blood-stream trypanosomes lose their infective power and their typical shape and become transformed into the crithidial form.

We have tried to elucidate the factors responsible for those transformations and succeeded in inducing the development from culture to blood-stream form, by addition of vertebrate serum. We used *Trypanosoma mega*, a parasite of amphibians. This trypanosome has been kept through fifty subcultures in a serum-free medium[1].

Slide cultures were made with various media, examined under a phase-contrast microscope and as stained smears. In young, actively growing cultures, the flagellates multiply as round bodies, often clustering into regular-shaped rosettes. After a few days the rosettes disintegrate, and the crithidia become elongated and free-swimming (Fig. 2).

The addition of fresh toad serum agglutinates the crithidia and induces the development, after a day or two, of numerous trypanosoma forms with undulating membrane and posterior kinetoplast. In 1911, França[2] observed a similar phenomenon in *T. rotatorium*. This author transferred crithidia from the digestive tract of a leech into frog serum kept continuously agitated. He ascribed the transformation to the agitation and not to the serum.

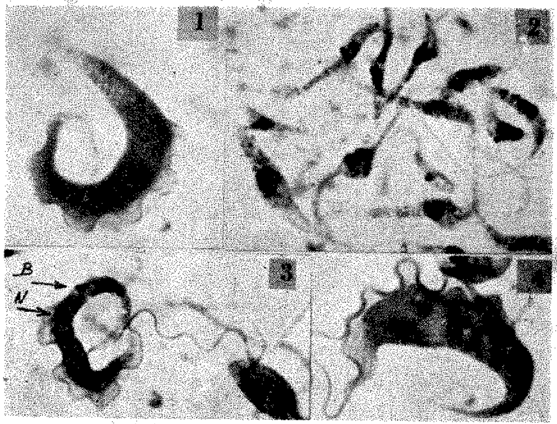

Fig. 1. Induced transformation of *Trypanosoma mega*: 1, blood-stream form in *Bufo regularis*; 2, culture form, crithidia; 3, trypanosoma form induced by toad serum; 4, trypanosoma form induced by calf serum. (Giemsa stain. × *c.* 1015)

We next noticed that the action was not specific of toad serum: the sera of various mammals, such as mouse, horse, calf, had the same action on the crithidia. This led us to choose calf serum for our next experiments.

Calf serum added to the culture medium in adequate proportion (50 per cent or more) agglutinates and kills the flagellates in a few minutes. The same serum heated to 56° C. for 30 min. agglutinates without lethal effect and, 24 hr. after its addition, numerous blood-stream forms appear in the culture (Fig. 4). Finally, this serum, exposed at 0° C. to large quantities of culture flagellates, has lost its specific agglutinins but retains its ability to change crithidia into trypanosoma form.

After dialysis, calf serum loses none of its form-changing activity. On the other hand, the serum fraction soluble in 50 per cent ethanol does not modify the form of culture crithidia.

The serum proteins were next fractionated by salting out with ammonium sulphate, followed by dialysis and lyophilization. Preliminary experiments showed that the activity is linked with the globulin fraction.

We observed that, in a culture, a certain number only of the crithidia were transformed into trypanosomes by the action of serum. This percentage seems to be closely connected with the age of the culture: a young culture, rich in dividing forms (rosettes), yields only very few trypanosoma forms. This would mean that, apart from the specific property of the serum, the transformation of the trypanosome requires a corresponding intrinsic factor. An analogy exists between this fact and the appearance of metacyclic trypanosomes at the end of the invertebrate cycle.

Relationship between the Amine Contents of the Two Adrenal Glands of the Cat

Workers[1] vary in their methods of calculating the adrenaline and noradrenaline content of adrenal glands. Some express them in micrograms per unit weight of gland, some in micrograms per gland and some even in micrograms per kilogram of body-weight. Since, frequently, there is a difference between the weight of the left and of the right gland of each cat, it was thought desirable to determine whether the percentage of noradrenaline is the same in the two glands, and whether the total amine content is the same for both glands or whether the heavier gland contains more amine.

Both adrenal glands from thirty-six adult cats were dissected free of connective tissue, and 50 mgm./ml. extracts were prepared in $0 \cdot 1\,N$ hydrochloric acid. The adrenaline and noradrenaline content of each extract was assayed biologically, using the cat blood pressure and nictitating membrane as test preparations. The results were calculated by the formula of Bülbring[2]. At least two determinations were made on each preparation and the results were treated statistically.

As can be seen from Fig. 1, the percentages of noradrenaline in the right and left glands are equal. From the thirty-six pairs of results the mean percentage of noradrenaline in the left gland was 44·5 per cent and in the right gland was 44·0 per cent. The correlation between the pair of glands is independent of the degree of methylation and of any difference in the weight of the two glands.

In some cats, the two adrenals may not vary by more than a few milligrams. However, in others the difference may be considerable. In this series of experiments the greatest absolute difference in weight was 52 mgm. and the greatest difference, expressed as a percentage, was 36·4 per cent. In other experiments[3], absolute differences as great as 100 mgm. were observed.

As can be seen from Fig. 2, where the results from glands which differed in weight by more than 1 per cent are recorded, there is a much closer correlation between the amount of amine in the two glands when expressed as per gland than when expressed as per 100 mgm. of gland. This is true whether the difference in the weight of the two glands is small or large. Although only mean results are shown in the above two figures, the results from individual pairs of glands show the same picture.

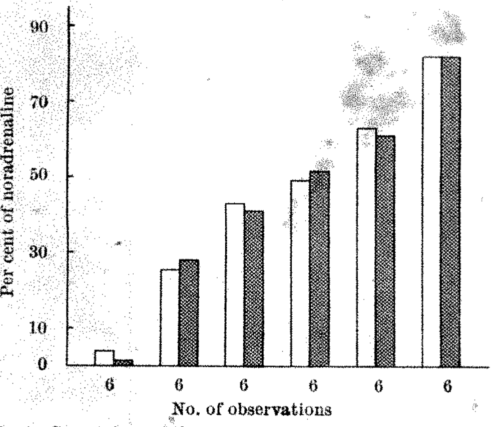

Fig. 1. Comparison of the percentage of noradrenaline in the left and right adrenal glands of the adult cat. The hatched area represents the left gland and the shaded area the right gland

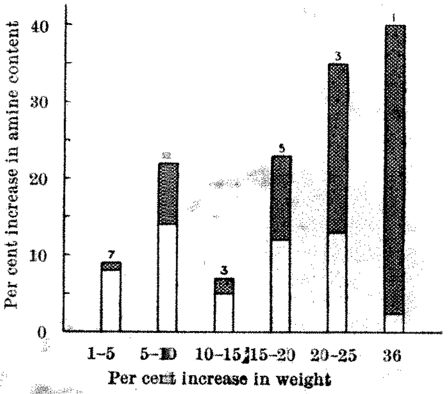

Fig. 2. Comparison of the amine contents of the two adrenal glands of the cat. The shaded area represents the difference in the amine content of the right and left glands, expressed as per 100 mgm. of gland, and the clear area represents the difference expressed as per gland. In all cases the difference is expressed as a percentage increase. The number above each column is the number of observations from which the mean value was obtained

Thus it may be concluded that, in the cat, the adrenaline and noradrenaline content of the two adrenal glands should be calculated as per gland and not as per unit weight of gland. This is of importance when one gland of the animal is used as a control and the effects of drugs on the other are studied[3].

Comparative Hyperfibrinogenæmic Action of D- and L-Adrenaline

In a previous work on the hyperfibrinogenæmic effect of several sympathomimetic amines, it was reported[1] that adrenaline, when injected subcutaneously into the rat, has the highest activity in increasing blood plasma fibrinogen. We have now compared the activity of D- and L-adrenaline in relation to the hyperfibrinogenæmic response. After a preliminary experiment to find roughly the relative hyperfibrinogenæmic effect of the two forms of adrenaline, the following experiment was carried out. Forty female albino rats of 150–200 gm. body-weight were divided by randomization into four groups of ten rats each. Two groups received subcutaneously respectively 0·03 and 0·06 mgm. of adrenaline (expressed as base)/100 gm. body-weight. The other two groups were injected respectively with 1 and 2 mgm. of D-adrenaline (base). 24 hr. later, the rats were bled from the aorta under pentobarbitone-sodium anæsthesia (4 mgm./100 gm. body-weight) using syringes coated with 'Dry Film 9987', clotting being prevented by the addition of 0·01 ml. of 30 per

Table 1

Substance	Dose (mgm./100 gm.)	Fibrinogen (mgm./100 ml.) ± stand. error
L-Adrenaline	0·030 0·060	285 ± 17·6 343 ± 17·4
D-Adrenaline	1·0 2·0	285 ± 17·2 338 ± 20·3

cent potassium oxalate per ml. of blood; the D- and L-adrenaline were Winthrop Research Products. The fibrinogen was determined by the classical technique of Cullen and Van Slyke, with ashing by the method of Campbell and Hanna[2], distillation and titration of ammonia. The results are summarized in Table 1. The relative potency of D-adrenaline as compared to L-adrenaline was calculated by standard statistical methods for a four-point assay. Our results indicate that the dextro-compound has 2·8 per cent of the activity of the lævo-compound, with the exact fiducial limits of 1·8 and 5·9 per cent. This potency ratio of 1 : 36, obtained for the hyperfibrinogenæmic effect of the dextro-compound in relation to the lævo-compound, is lower than the ratio 1 : 20 obtained by Tainter[3] for the pressor response in the cat. It is, however, comparable to the 1 : 30 to 1 : 40 ratio found by Fromherz[4] for the pressor response in dogs.

We thank Winthrop Products, Inc., New York, for the gift of the D- and L-adrenaline.

Photoperiodism and Thermal Resistance of Goldfish

IT is well known that the resistance of fish to extremes of heat or cold can be markedly altered by acclimatizing them to progressively higher or lower temperatures. In an attempt to discover the mechanism involved, it became evident that several factors in addition to thermal acclimatization may alter the resistance of goldfish to extreme temperatures. Diet[1] and size, sex and season[2] affect the thermal resistance of goldfish maintained at a constant temperature of 20° C.

Factors responsible for the seasonal differences are being investigated. Over a period of several years, goldfish maintained at a temperature of 20° C. and fed on a standard diet were relatively more resistant to cold in winter and to heat in summer. Cyclical seasonal changes in thermal tolerance seem to be at least partially independent of environmental temperatures. Since the seasonal variation in length of day was the only obvious environmental variable, experiments were designed to test the effects of different photoperiods.

In October 1955 two groups of goldfish (mean weight 14·2 gm.) were subjected to different photoperiods. The first group received 8 hr. illumination (70 ft. candles at the water surface) and 16 hr. darkness, while the second group received 16 hr. illumination (same intensity) alternating with 8 hr. darkness. The first situation corresponded to the hours of sunlight in winter, and the second to the sunlight period of summer. Temperatures varied from 18° to 20° C. in the room but were the same in all tanks. The diet was pablum and shrimp meal.

The thermal resistance of the two groups was compared after forty days and after fifty days. In tests of thermal resistance, the two groups (marked by distinctive fin clips) were placed together (fifteen of each group) in a lethal-temperature bath. The temperature in the cold bath fell from about 4° C. to 1° C.; that of the warm bath was about 36·5° C. Other details of testing were similar to those given elsewhere; fish here referred to as 'killed' or 'dead' are actually 'removals'.

In Table 1 we have recorded the number of minutes exposure required to kill different percentages of the samples. Thus, in the heat test *A*, 25 per cent of the short-day fish were dead at 31 min., while the same percentage of long-day fish survived until 41 min.—a difference of 10 min. in the 25 per cent lethal times. The temperature of the lethal bath at 41 min. was 36·5° C.; the initial temperature of this bath was 34·5° C. In the cold test, carried out at the same time, 25 per cent of the sample of short-day fish were dead at 198 min., while the same percentage of long-day fish had died at 102 min. The temperature of the bath at 198 min. was 1·2° C.

In detail, the table shows that the short-day period fish (winter fish) are consistently more resistant to cold and less resistant to heat, whereas the reverse is true of the long-day period fish (summer fish). The precise differences in lethal times may be varied by changing the severity of the test, as shown by the two sets of lower lethal temperature data. In each case, however, the thermal tolerance of the two groups of fish differs in a manner similar to the seasonal variations described elsewhere[2]. It is concluded that the seasonal variations in thermal

Hormonal Depression due to Treatment of Animals with Chlorpromazine

IN an earlier paper, we have shown that in human patients chlorpromazine impairs the hypothalamus and through it the anterior pituitary lobe[1]. This depressing effect balances itself in accordance with the push–pull principle so far as the following tropins are concerned: follicle-stimulating hormone, luteinizing hormone, adrenocorticotropic hormone and thyroid-stimulating hormone, since they produce secondary hormones. This is impossible, however, with regard to luteotropic hormone and somatotrophic hormone, as neither of them produces peripheral secondary hormones.

The present communication describes the endocrine effects after three months of continuous treatment with chlorpromazine in animals which received subcutaneously 10 mgm./kgm. daily. For every group, five rats were used and the weights of their organs are given as average values. A detailed histological report on these effects will be published in collaboration with Prof. H. Ungar.

Follicle-stimulating hormone. (*a*) In infantile female rats it is only partly suppressed, as evidenced by spontaneous opening of the vagina on maturation and later by a tendency to permanent œstrous; the ovaries weighed 35 mgm. (controls 90 mgm.).

(*b*) In the male rat, the suppression is strong enough to produce atrophy of the testes (700 mgm. instead of 1,500 mgm.).

Luteinizing hormone. (*a*) In the female rat, suppression is complete, as no corpora lutea are formed.

(*b*) In the male rat, the suppression of interstitial-cell stimulating hormone is also complete, as the prostate and seminal vesicles become atrophied (500 mgm. instead of 2,000 mgm.).

Adrenocorticotropic hormone. In both sexes, the suppression is marked, as the adrenals weighed on an average 35 mgm. (control 45 mgm.).

Thyroid-stimulating hormone. In both sexes suppression is slight, since the thyroid glands weighed 28 mgm. as compared with the control (34 mgm.).

Somatotrophic hormone. In both sexes growth was definitely stunted by treatment. The females reached a steady weight at 95 gm. (controls, 125 gm.); the males at 125 gm. (controls, 200 gm.).

Subcutaneous injections of 5 rabbit units somatotrophic hormone (Wilson) daily along with the chlorpromazine treatment restored the weight within two months.

Luteotropic hormone. This hormone was tested in rabbits which received daily 0·5 mgm. progesterone. The second phase of the endometrium, which disappears normally after seventeen days treatment, was preserved for thirty-four days and longer by additional injections of chlorpromazine. This seems to indicate endogenous production of luteotropic hormone. Hence luteotropic hormone shows a pattern of reaction different from that of all other tropins[2].

After three months treatment there are no differences in pituitary weights between the animals treated with chlorpromazine and their controls (10 mgm.).

The fact that chlorpromazine was able to suppress the growth hormone may indicate that somatotrophic hormone is balanced by a secondary peripheral hormone. It has been suggested that such a relation exists with glucagon.

The above findings confirm the current view that chlorpromazine depresses the function of the hypothalamus. The endocrine disturbances thus brought about in the pituitary of animals may also appear in man if dosage is excessive.

We wish to thank the Specia Co., Paris, which supplied the Largactil, and the Wilson Laboratories, Chicago, which supplied the growth hormone. Our thanks are also due to Messrs. E. Zawojski, A. Eviatar and O. Hinckley for assistance.

Intracellular Distribution of Choline Acetylase

WITH the development of methods for the measurement of choline acetylase independently of the enzymic formation of acetyl-coenzyme A[1–3], it has become possible to determine the intracellular distribution of the enzyme. In the present experiments, rabbit brain homogenates in 0·25 *M* sucrose were fractionated by differential centrifugation. In exp. 1 the procedure of Brody and Bain[4] was followed; in exp. 2, somewhat different centrifugal forces were applied as shown in Table 1. Each particulate fraction was washed by resuspension in 0·25 *M* sucrose and recentrifugation at the same speed; the washings were then pooled with the original supernatant for the next stage of the centrifugation.

Choline acetylase activity was determined by incubating the fractions in a system in which the substrate acetyl-coenzyme A had already been formed during a preliminary incubation at 37° C. of aged pigeon liver enzyme with citrate, acetate, choline acetylase and adenosine triphosphate[2,3]. After this induction period of 10 min. for the formation of acetyl-coenzyme A, the brain fraction to be tested was added to the system, incubation continued for a further 60 min. and the amount of acetylcholine formed determined by assay (frog rectus abdominis).

Whole homogenates tested in this way have only one-quarter to one-half of the activity of extracts made from acetone-dried brain. However, when they are treated with ether (0·2 ml./ml.), a procedure used in earlier studies on the synthesis of acetylcholine[5,6], the activity of the homogenates is equivalent to that obtained with acetone powders. The

isolated fractions are also maximally active only after ether treatment, and the results shown in Table 1 refer to values so obtained.

The results given in Table 1 show that the sum of the activities of the separate fractions is equivalent to about 90 per cent of the activity of the whole homogenate. The fraction with the highest activity is that sedimented at 12,000–15,000 *g*. Using biochemical and histological criteria, Brody and Bain[4] obtained evidence that this fraction of rabbit brain homogenates contains only mitochondria; histological examination of our preparations confirms this finding. The mitochondrial fraction contains 50–70 per cent of the enzyme activity. Evidence that the enzyme is firmly bound to the particles sedimented at 12,000–15,000 *g* has been obtained by demonstrating that little or no activity is lost from this fraction after repeated washing. The only other fraction containing an appreciable proportion of the activity is the final supernatant (21–28 per cent); the remaining activity is distributed between the other fractions.

This evidence for the presence of choline acetylase in mitochondria is a further step in understanding the metabolism and function of acetylcholine in nervous tissue.

Cholinesterase and Sodium Transport by Frog Muscle

IN a variety of tissues (frog skin[1], red cells[2], *Chironomus* anal papillæ[3], and *Eriocheir* gills[3]) the active transport of sodium is blocked by inhibitors of cholinesterase. This communication concerns the role of cholinesterase in the sodium pump of the sartorius muscle of the frog, *Rana pipiens*. Sodium transport is readily demonstrated by placing the muscle in a Ringer's solution in which one-half of the sodium chloride has been replaced by sucrose[4]. Though the concentration of sodium in this sodium-deficient Ringer's still exceeds that within the muscle fibre, the muscle responds by actively transporting sodium ions into the external medium, so that after 30 min. the sodium content of the muscle, measured by flame photometry, has markedly decreased.

Table 1. THE SODIUM CONTENT OF MUSCLES AFTER 30 MIN. IN SODIUM-DEFICIENT RINGER'S AT 25° C. SODIUM DETERMINED BY FLAME PHOTOMETRY; MUSCLE WATER DETERMINED BY THE DIFFERENCE BETWEEN WET AND DRY WEIGHTS OF THE MUSCLE

Inhibitor	Sodium (m.equiv./kgm. muscle water) ± S.E.
None	23 ± 1
Previously exposed for 15 min. to 5×10^{-4} *M* hexaethyl tetraphosphate	35 ± 2
10^{-3} *M* physostigmine in sodium-deficient Ringer's	34 ± 2
Exposed to 10^{-3} *M* physostigmine for 30 min., washed and transferred to sodium-deficient Ringer's	22 ± 3
10^{-3} *M* prostigmine in sodium-deficient Ringer's	25 ± 2

This decrease in sodium content was prevented by previous exposure of the muscle to the irreversible anti-cholinesterase hexaethyl tetraphosphate, or by the addition of the reversible inhibitor physostigmine to the sodium-deficient Ringer's (Table 1). The block produced by physostigmine was reversed when the muscles were washed after exposing them to the inhibitor. However, a third anti-cholinesterase, prostigmine, failed to block sodium extrusion. Since it is known that quaternary nitrogen compounds, like prostigmine, are unable to penetrate the membranes of excitable tissues[5], we can conclude that only the anti-cholinesterases which penetrate into the muscle fibre and inhibit the intracellular enzyme are capable of blocking the sodium pump.

Though these experiments suggest that inhibitors of intracellular cholinesterase block sodium extrusion, they do not establish that cholinesterase participates in the pumping mechanism. Inhibitor studies, as Danielli has stressed[6], must be supported by evidence showing that the inhibitor actually does lower the activity of the enzyme and that the decrease in enzymatic activity is paralleled by a decrease in the rate of active transport.

Therefore, the effects of graded concentrations of physostigmine on the transport of sodium and on the activity of cholinesterase were measured. As is shown in Fig. 1, when the concentration of physostigmine was decreased the amount of sodium

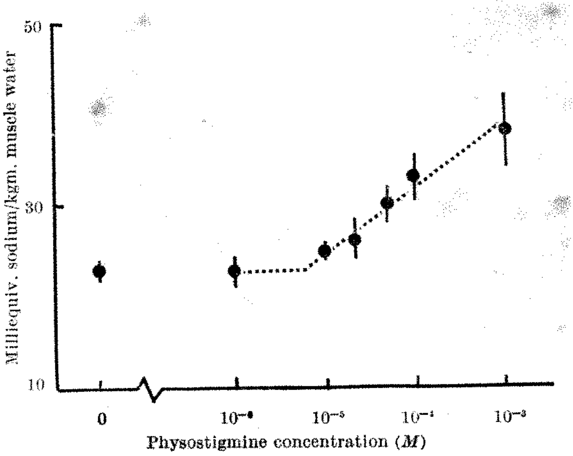

Fig. 1. The mean sodium content of the muscle water—after 30 min. in sodium-deficient Ringer's—as a function of the concentration of physostigmine. In every experiment 10^{-3} *M* prostigmine was present. The line between 10^{-3} *M* and 10^{-5} *M* physostigmine was calculated by the method of least squares. The vertical lines on the points indicate the standard errors

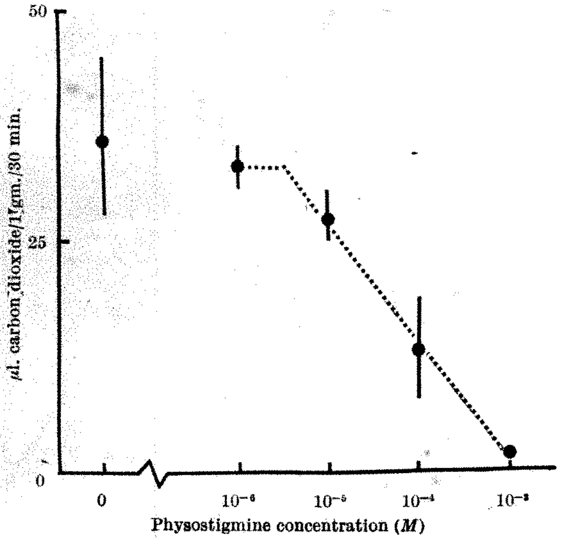

Fig. 2. The mean cholinesterase activity of muscles as a function of the concentration of physostigmine. Activity was measured gasometrically with 0·015 *M* ethylchloroacetate as the substrate. In every experiment the medium contained 10^{-3} *M* prostigmine and the muscles were exposed to the inhibitors for 60 min. before the addition of the substrate. Symbols and method of plotting as in Fig. 1

remaining in the muscle decreased, until in 10^{-5} *M* physostigmine the sodium transport was scarcely affected. The measurements of cholinesterase activity were also taken on intact muscles, using ethylchloroacetate as a substrate[7]. Ethylchloroacetate can penetrate into the muscle fibres, and therefore the cholinesterase activities of intact muscles and of homogenates, when measured with this substrate, are almost identical. The results are presented in Fig. 2. In each instance 10^{-3} *M* prostigmine was also present to inhibit the extracellular cholinesterase which, though it makes up 40–60 per cent of the total enzyme activity, has already been shown to be unimportant in sodium transport. However, the concentrations of physostigmine which inhibited sodium extrusion produced a comparable inhibition in the activity of the intracellular cholinesterase. In fact, the concentrations of physostigmine producing a 50 per cent inhibition of sodium transport and a 50 per cent inhibition of intracellular cholinesterase were almost identical.

The sodium transport in frog muscle was also inhibited by iodoacetic acid[4]. As is shown in Table 2, iodoacetic acid is not as effective an inhibitor as are the anti-cholinesterases. Moreover, the block produced by iodoacetic acid was by-passed by adding pyruvate to the medium. In normal circumstances the sodium pump was scarcely affected by cyanide, but this inhibitor was strongly effective when iodoacetic acid and pyruvate were present. Clearly any source of high-energy phosphate bonds is sufficient: either glycolysis in the presence of cyanide or the Krebs cycle when pyruvate is available.

Table 2. THE SODIUM CONTENT OF MUSCLES FOLLOWING 30 MIN. AT 25° C. IN SODIUM-DEFICIENT RINGER'S WHICH CONTAINED METABOLIC INHIBITORS

Inhibitor	Sodium (m.equiv./kgm. muscle water) ± S.E.
10^{-3} *M* iodoacetic acid	28 ± 1
10^{-3} *M* iodoacetic acid; 10^{-3} *M* pyruvate	23 ± 2
10^{-3} *M* potassium cyanide	25 ± 1
10^{-3} *M* iodoacetic acid; 10^{-3} *M* pyruvate; 10^{-3} *M* potassium cyanide	34 ± 3

In summary, the present data indicate that the activity of cholinesterase is prerequisite for the working of the sodium pump in muscle. It is apparent that a source of high-energy phosphate bonds is also essential, though the means by which this energy is invested in the transport of sodium remains obscure.

This study was aided by Grant *B*-703, from the Institute of Neurological Diseases and Blindness, of the National Institutes of Health, Public Health Service.

A Simple and Effective Movement-restricting Collar

IT is frequently vital in research to restrict the experimental animal's movements and to keep him from damaging the experimental site, such as an externalized organ, tube or catheter. Much valuable work and time is often nullified in a short time by the animal pulling at the operative site which he will invariably do if he has access to the area.

In our work on ureteral regeneration it is necessary to prevent the dog from reaching and pulling the ureteral splint which is necessarily exposed on the flank for six weeks. Muzzles, pneumatic collars, disk collars and heavy dressings have been employed without success and with some discomfort to the animal as they would constantly worry the restricting apparatus. Since 60–70 per cent of our original operated animals pulled their tubes, a new collar was devised and has proved very satisfactory during the past eight months.

A template of heavy wrapping paper is made to fit to the size of the dog (Fig. 1). The measurements to fit the various size dogs from the smallest to the largest are accomplished with comparative ease as the collar is sufficiently adaptable in three sizes from large to small. This is traced on 18-gauge aluminium, which cuts easily with tin shears. $\frac{1}{8}$-in. holes can be drilled or punched with a common nail. The holes are measured at one and one-half inch intervals and one inch from the edge of the entire periphery. These are made to hold felt or sponge rubber, and we have found the former to hold best. Continuous No. 10 cotton thread holds up well under most conditions. At the ends, four $\frac{1}{8}$-in. holes are made on the overlapping end and two or three rows are made on the underlying flap. This gives an additional chance for adjustment or to use the collar on other animals. Two large holes, $\frac{1}{2}$ in., are made at the point of the collar to permit the fastening of the chest ropes. This is an essential part of the collar to prevent rotation, as the collar is made to allow the dog free access of motion in all quadrants except the operation site. The flange can be changed or moved to suit the need. The chest band can be simply a short rope

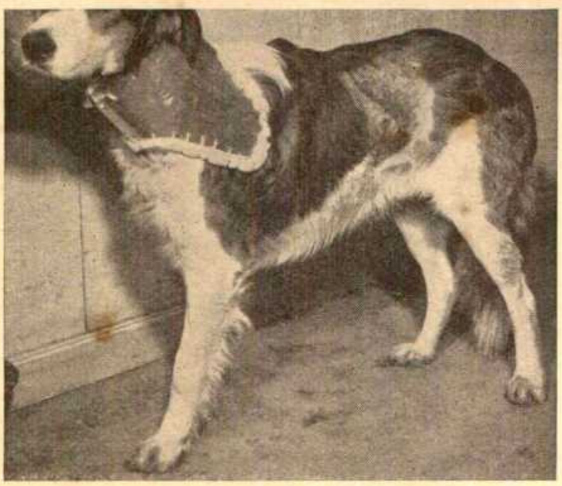

Fig. 1. Dog with movement-restricting collar attached. Note the flange extends well over the scapula

placed through the ½-in. hole on one side of the collar and brought across the chest in the back of and between the fore-leg to the hole on the opposite side of the flange. A canvas strap three inches wide with metal loops to accommodate snaps or short leather thongs which are crossed under and between the forelegs can be employed as an alternative to the rope.

This collar has proved very satisfactory by first being well tolerated by laboratory animals under conditions of restricted quarters. The dog fretted very little and apparently had sufficient latitude of movement to enable reasonable activity and comfort in eating and resting. These dogs were observed for a continuous six-week period, at the end of which time the fur and skin under the collar was not irritated in any way.

The optimum requirements for such a collar are for the lightest possible material which would produce the least amount of bulk. The only other effective type is the disk collar, but it was seen in our series of animals to be only 30 per cent effective against 92 per cent with the wrap-around type. A comparison of some values shows the disk type to weigh 1¾ lb. against 8 oz. Moreover, the cost of the latter is much lower. The ease of application and construction is far greater in the wrap-around and it can be changed rapidly if the occasion demands.

Two factors have to be avoided : (1) To make the strings to the chest strap secure, as without these the collar can rotate on the neck, thus allowing the animal access to the protected site. (2) To make the flange sufficiently long to restrict motion successfully.

This investigation was supported by a research grant (*RG* 4300) from the National Institutes of Health, Public Health Service.

Prophylaxis of Trypanosome Infections in Cattle

THE introduction of 'Ethidium' (I) in 1952 made available to veterinarians in Africa a drug with very high therapeutic activity against the two most important trypanosomes of cattle, *Trypanosoma congolense* and *T. vivax*, and this drug is now widely used. There still seemed to be the need, however, for a drug which would confer a prolonged period of protection to dosed animals, and we have therefore, worked to this end. One particular series of drugs (II) showed, in mice, therapeutic activity of a very high order, and also a prophylactic action greater than that of any other drug available. Two of the most active of this series, '*R.D.* 2787' and '*R.D.* 2801', were sent to Africa for trials in cattle. '*R.D.* 2801', which had appeared the better of the two in tests in mice, has shown considerable promise in tests in Tanganyika and in Nigeria, against both *T. congolense* and *T. vivax*. In one trial, for example, a single dose of 2 mgm./kgm. protected cattle for at least six months. Trials are still in progress, and full results of both these trials and of our laboratory findings will be published elsewhere.

Dehydrochlorination of DDT by Resistant Houseflies and Mosquitoes

THE recent characterization of DDT dehydrochlorinase in resistant houseflies[1] has prompted an investigation of this enzyme and of the production of 2,2-bis(*p*-chlorophenyl)-1,1-dichloroethylene (DDE) in mosquitoes, in which DDT-resistance is now developing[2]. As an initial step, two strains of resistant houseflies were assessed for DDT-dehydrochlorinase content. The DDT-45 strain showed no less activity than originally reported[1], the DDE production in 3 hr. by the equivalent of six flies averaging 98 μgm. for homogenates and 52 μgm. for acetone powders. The Dilan strain, developed by two years of dilan pressure without any exposure to DDT, showed an enzymic DDE production of 100 μgm. for homogenates and 34 μgm. for acetone powders. This Dilan strain resembled the DDT-45 strain in having an *LD*90 exceeding 50 μgm. and being able to convert 90 per cent of 10 μgm. of DDT topically applied to DDE in 24 hr.

Two instances of DDT-resistance in mosquitoes were then investigated. (1) Resistant salt-marsh mosquitoes (*A. taeniorhynchus* admixed with *A. sollicitans*) from Cocoa Beach, Florida, where DDT-resistance was first reported in 1949 and which has since been liberally treated with lindane, dieldrin and heptachlor[3]; they were compared with salt-marsh mosquitoes from the Oatland Island marshes, Savannah, Georgia, where DDT has never been used. (2) Resistant *Aedes aegypti* from El Socorro and Aranguez[4], Trinidad; they were compared with a normal laboratory stock (*CD* strain) obtained from Camp Detrick, Maryland.

The susceptibility of these strains was determined by exposing fourth-instar larvæ for 24 hr. to various concentrations of DDT added in 1 c.c. of acetone to 1 litre of tap water in enamel pans. The *LC*50 values were thirteen times greater than normal for the salt-marsh mosquitoes from Cocoa Beach, and five hundred times greater than normal for the *A. aegypti* from Trinidad. Accordingly, 140–200 larvæ of each strain were exposed to DDT in three 1-litre pans of tap-water for 24 hr., and their DDT uptake and DDE production were determined by the Schechter–Haller method after washing them in a stream of distilled water, grinding them in a mortar with sand and anhydrous sodium sulphate, extracting with carbon tetrachloride and purifying in a 'Celite'-sulphuric acid column.

Table 1

	A. taeniorhynchus		*A. aegypti*	
	Normal	Resistant	Normal	Resistant
*LC*50, p.p.m. DDT	0·003	0·04	0·004	2·0
Larvæ exposed, No.	140	140	200	150
Concentration, p.p.m. DDT	0·005	0·03	0·003	1·0
DDT uptake (μgm.)	5·6	73·3	2·0	1,553
DDE produced (μgm.)	2·4	15·9	1·3	149·3

Both normal strains produced an insignificant amount of DDE, their uptake of DDT being small. The resistant strains, exposed to higher concentrations, accumulated much DDT; the resistant *A. aegypti* took up slightly more than one half the 3 mgm. of DDT to which the 150 larvæ were exposed. Both resistant strains produced considerable amounts of DDE, the ratio DDE/DDT being 22 per cent for the salt-marsh mosquitoes and 10 per cent for *A. aegypti*. On the average, one larva of the resistant *A. aegypti* produced approximately 1 μgm. of DDE in 24 hr. In comparison, an adult housefly of the *DDT*-45 strain, which weighs 4·5 times as much, can produce 4·5 μgm. of DDE per 24 hr. from DDT topically applied[5].

DDT-dehydrochlorinase activity was then assessed by means of acetone powders and homogenates at various concentrations incubated with DDT in ethanol or on glass beads. A total of thirteen such tests were made, but in no case was there any significant production of DDE. It is therefore suggested that the DDT-dehydrochlorinase of these mosquitoes requires different conditions from these suitable for housefly material. This view is supported by the recent observation of Kearns that homogenates of the resistant Mexican bean beetle, *Epilachna varivestris*, will not produce DDE under conditions suitable for the housefly, but can be induced to do so by a mixture of eighteen ions and compounds selected for their liability to activate or protect against inhibition (Kearns, C. W., personal communication).

The detailed results of this investigation are being made available by the World Health Organization.

Carotenoids and Reproduction in *Pyronema confluens*

Robinson[1] found that light was necessary for both orange pigmentation and fruit-body (apothecium) formation in *Pyronema confluens* Pers. ex Tul. Since he was unable to obtain these effects separately, he postulated a causal relationship between them. Later work on the effects of light on *Pyronema*[2] has not been concerned with testing this hypothesis. Recent work by one of us[3] has shown that there is no direct relationship between pigmentation and spore production in *Fusarium oxysporum*, and it appeared useful, therefore, to investigate the problem in *P. confluens*.

Apothecium formation was observed using a double-dish technique[4]; the inner dish contained a medium favouring vegetative growth (Czapek–Dox agar with 2 per cent glucose) and the outer dish a medium favouring reproduction (plain agar). Inoculation of the inner dish with wild-type *P. confluens* and exposure either to daylight or to a lamp emitting light between 360 and 580 mμ gave rise to a faintly orange mycelium, and to orange apothecia in the outer dish.

Exposure of the *P. confluens* to a lamp emitting ultra-violet radiation between 300 and 400 mμ produced a white mycelium and white apothecia. When grown in darkness, the mycelium was again not coloured; but in this case no apothecia were formed.

The pigments, both from coloured apothecia produced as described, and from surface mycelial mats, without apothecia, grown in the light in Roux bottles containing a liquid Dox medium with 5 per cent glucose, were extracted with cold acetone. The pigments were transferred into light petroleum by addition of water. After saponification with methanolic potassium hydroxide and partition with water and petrol two groups of pigments were found. One was present in the petrol and the other remained in the alkaline hypophase.

Chromatographic analysis of the epiphasic portion showed that it contained five pigments of which four have been identified. They are β-carotene, γ-carotene, torulene and a *cis*-isomer of the latter, probably neo-torulene[5]. This component was slightly less adsorbed than torulene; its absorption spectrum (maxima 451, 477 and 509 mμ in light petroleum) yielded on iodine catalysis a curve indistinguishable from that given by torulene under similar conditions (455, 480 and 511 mμ). The fifth component, which has a similar absorption spectrum (maxima 456, 484 and 516 mμ in light petroleum) to that of torulene, could not be separated, on chromatograms of either calcium carbonate or cellulose powder, from a celaxanthin-like fraction[6] we have isolated from berries of *Celastrus rosthornianus*.

The hypophasic pigments were extracted with petrol after acidification of the methanolic alkali. The absorption spectrum of the total fraction corresponded with values given for torularhodin, an acidic carotenoid fraction found in various Rhodotorulae[7]. We were able to separate this fraction into two major bands using an adsorption chromatogram of cellulose powder. The two fractions had similar absorption spectra, the maxima (in light petroleum) being: lower band, 496 and 526 mμ, inflexion at 460 mμ; upper band, 497 and 530 mμ, inflexion at 460 mμ.

Fractions similar to both these acidic compounds have been found in cultures of *Rhodotorula rubra* (J. F., unpublished observations).

Bean and Brooks[8] reported an albino *Pyronema* capable of normal reproduction. We have produced an albino mutant by exposing ascospore suspensions to an ultra-violet lamp emitting mainly at 254 mμ. The albino mutant required light to produce apothecia; but on examination of the acetone extracts no colourless polyenes were found. We were also unable to detect colourless polyenes in unilluminated cultures of either wild-type or albino *P. confluens*.

We conclude that in *Pyronema confluens* we have two distinct and unrelated photochemical effects. One leads to the synthesis of carotenoids and the other to the formation of apothecia. As a result of these observations we suggest that Robinson's hypothesis is invalid.

We wish to thank Drs. E. C. Bate-Smith, N. F. Robertson and T. Swain for their interest in this work. For one of us (J. F.) the work described in this paper forms part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Isolation of Plant Starches

In the course of studies on the apple fruit, the need arose for a quantity of apple starch. None of the published methods of preparation we tried was entirely satisfactory, and a simple, rapid method was evolved which seems to have a general application. Starches have been prepared from a number of materials, which are listed in Table 1, together with the nitrogen content of the starches.

Table 1

Source	Nitrogen (per cent dry wt.)	Source	Nitrogen (per cent dry wt.)
Green apple	<0·01	Chestnut	0·02
Green tomato	<0·01	Butternut root bark	<0·01
Carrot	0·03	Sumac bark	0·06
Potato	0·03	Marigold leaves	0·06
Wheat (mature)	0·05	Tobacco leaves	0·02
Maize (mature, soaked)	0·06		

The tissue was ground in a Waring blendor with sufficient cold 1 per cent solution of ammonium oxalate to produce a thin mixture, which was then filtered through muslin. This process was repeated on the residue. Occasionally a third extraction was required in order to remove the starch completely. The suspension was centrifuged in conical tubes at 200–300 *g*. Starch became packed in a tight layer at the bottom, and impurities were readily removed from its surface by gentle washing. The starch was suspended in water, centrifuged out at about 1,500 *g* and the surface washed. This was repeated: a total of four or five times was sufficient for the materials listed in the table. The presence of impurities on the surface of the starch layer was easily seen. Occasionally a small amount of impurity settled below the starch. This was removed by suspending the whole in a small amount of water and centrifuging three or four times for a few seconds, the suspension being poured each time into a clean tube. The purified starch was washed finally with alcohol and ether.

In polarized light all starches except those from leaves showed a characteristic maltese cross. The granules of the leaf starches were flat and showed rotation of polarized light only when viewed on edge. Examination of stained preparations of all samples indicated a high degree of purity and the granules were undamaged mechanically.

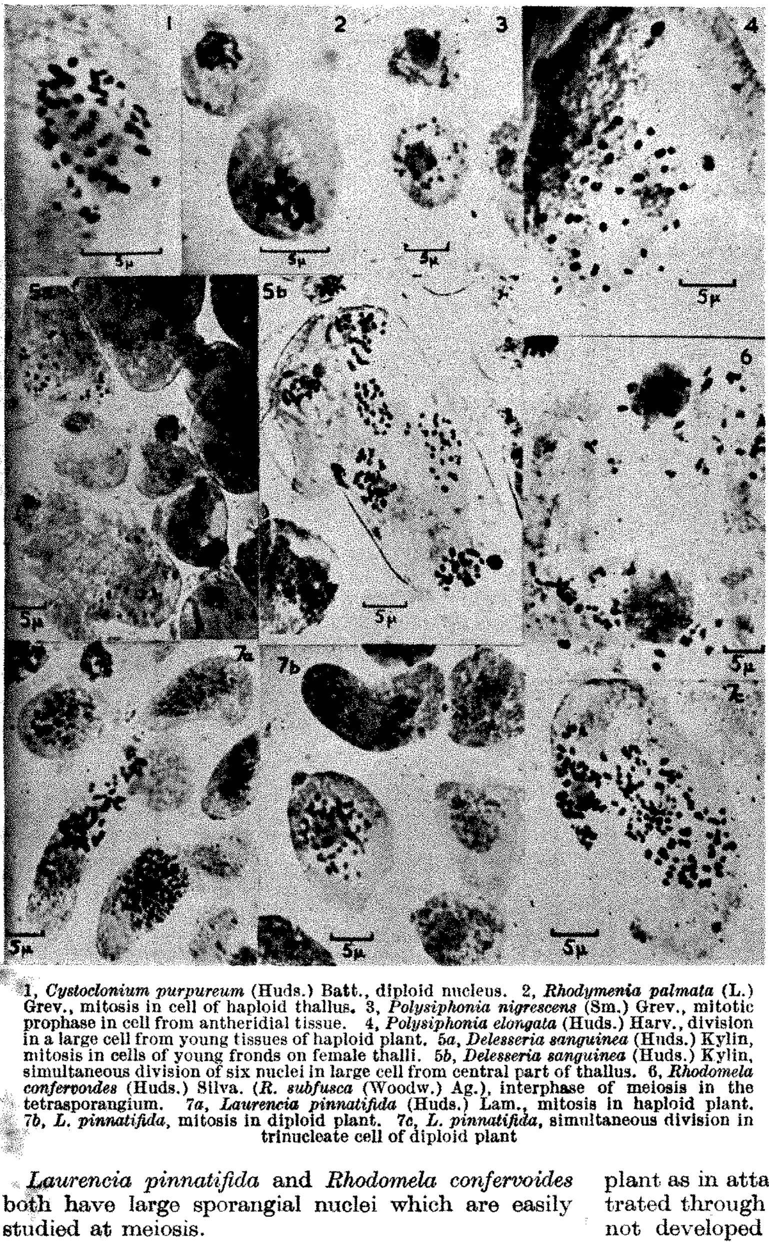
Chromosome Counts in the Rhodophyceae

Nuclei of the Rhodophyceae are often difficult to observe either on account of their small size, the presence of excessive mucilage or the cartilaginous nature of the tissues in which they occur. Using squash techniques and staining with ferric ammonium sulphate and aceto-carmine[1], or with aceto-carmine alone, both mitotic and meiotic divisions have been observed in a number of red algae.

January and February were found to be good months for obtaining rapidly growing tissues, antheridial material being especially suitable. Fixation was in acetic–alcohol (1 : 3) or Carnoy's fluid.

Chromosome counts of the following species, arranged according to the Preliminary Check List of British Marine Algae[2], have been made.

	n	$2n$	Previous counts (ref. 3)
Cystoclonium purpureum (Huds.) Batt.	—	50	—
Rhodymenia palmata (L.) Grev.	21	—	—
Ceramium rubrum (Huds.) Ag.	34	—	—
Cryptopleura ramosa (Huds.) Silva.	30	—	—
Membranoptera alata (Huds.) Stackh.	32	—	—
Delesseria sanguinea (Huds.) Kylin (ref. 4)	31	—	$2n = 40$
Laurencia hybrida (DC.) Lenorm ex Duby.	31	—	$2n = 40$
Laurencia pinnatifida (Huds.) Lam.	29	58	$2n = 40$
Polysiphonia elongata (Huds.) Harv.	37	—	—
Polysiphonia lanosa (L.) Tandy.	27	—	—
Polysiphonia nigrescens (Sm.) Grev.	30	60	—
Rhodomela confervoides (Huds.) Silva.	32	—	$2n = 40$



1, *Cystoclonium purpureum* (Huds.) Batt., diploid nucleus. 2, *Rhodymenia palmata* (L.) Grev., mitosis in cell of haploid thallus. 3, *Polysiphonia nigrescens* (Sm.) Grev., mitotic prophase in cell from antheridial tissue. 4, *Polysiphonia elongata* (Huds.) Harv., division in a large cell from young tissues of haploid plant. 5*a*, *Delesseria sanguinea* (Huds.) Kylin, mitosis in cells of young fronds on female thalli. 5*b*, *Delesseria sanguinea* (Huds.) Kylin, simultaneous division of six nuclei in large cell from central part of thallus. 6, *Rhodomela confervoides* (Huds.) Silva. (*R. subfusca* (Woodw.) Ag.), interphase of meiosis in the tetrasporangium. 7*a*, *Laurencia pinnatifida* (Huds.) Lam., mitosis in haploid plant. 7*b*, *L. pinnatifida*, mitosis in diploid plant. 7*c*, *L. pinnatifida*, simultaneous division in trinucleate cell of diploid plant

Laurencia pinnatifida and *Rhodomela confervoides* both have large sporangial nuclei which are easily studied at meiosis.

Apical Cell of Salt Marsh Fucoids

In 1950, S. Baker described the universal occurrence of a three-sided apical cell in a number of salt marsh fucoids[1]. Since no further publication on the anatomy of these plants has appeared, the following observations may be of interest.

On several occasions *Fucus vesiculosus* L. var. *muscoides* Cotton was collected from Clachan Sound, Argyllshire, where the plants form a tufted carpet stretching high up the shore together with *Armeria maritima*. An examination of these plants showed a series in development from those with a cylindrical thallus only 1 cm. in length which branched profusely in a very irregular manner to those 5 cm. or more in length, with branching confined to one plane and with a flattened thallus showing some differentiation into midribs and wings. Sections through the apices of these plants showed a parallel series in development. The smallest plants had a very shallow apical groove at the base of which no distinct apical cell could be discerned. Slightly larger forms had the apical groove lined with hairs but still no differentiation of a distinct apical cell. The smallest of the forms which showed a tendency to flattening of the thallus had a distinct three-sided apical cell such as Baker describes[1]. Sometimes this was accompanied by apical hairs still lining the apical groove. Small attached plants nearby had a four-sided apical cell, as is characteristic of the adult fucoid thallus. In fact, the apices of these plants of *F. vesiculosus ecad muscoides* demonstrated the successive stages through which the apex of the attached form of *F. vesiculosus* passes during its development from the sporeling to the adult thallus[2].

The retention of the juvenile form of the apex is accompanied by little secondary activity of the various tissues. Very rarely was any evidence of secondary cortex seen, and few, if any, secondary hyphæ were found. Where the latter did occur, they often arose in tufts from a single cell of the innermost cortex and ramified in all directions through the thallus and not mainly towards the base of the plant as in attached forms. Occasionally hyphæ penetrated through the base of the plant, but these were not developed in sufficient numbers to interweave and form an attaching disk.

Baker and Bohling[3] ascribed the origin of salt marsh fucoids to the production of adventitious branches from cast-up thalli, the branches separating with the decay of the parent plant. The anatomical structure of these plants of *F. vesiculosus* var. *muscoides* suggests the possibility that they originated from fertilized eggs which were cast high up the shore by spray and exceptional tides, into a zone unfavourable for normal growth and development. Under these conditions they survive and grow slowly, retaining the juvenile form and structure of the species and never reaching maturity and the formation of reproductive cells.

The Indo-Pacific Loggerhead Turtle in Tasmanian Waters

THERE appears to be only one published record of a chelonian in Tasmania[1], that of a leathery turtle, *Dermochelys coriacea* (Linné, 1766), which came ashore at Fortescue Bay in March 1889 (specimen in Tasmanian Museum, Hobart). From unpublished information supplied by Mr. John Fazackerly, it seems probable a large turtle observed by him to emerge from the sea at this locality in or about 1945 was a second example of this species.

We are now able to present reports of the appearance, within the past five years, of no fewer than eleven other turtles on the coasts of Tasmania—three entries being based on available specimens or parts thereof, the remainder on hearsay only. Material examined comprises: (1) skull of the first animal to come under our notice, a fairly fresh example found stranded by one of us (B. C. M.) about half a mile north of Mount Cameron West on November 24, 1951; (2) skull and greater part of the carapace from near the mouth of the Arthur River (Mr. Bailey, per Mr. M. Olsen, probably November 1951); (3) complete young animal from Adventure Bay, Bruny Island (Tasmanian Museum, Hobart, August 24, 1955). These have been determined as the Indo-Pacific red-brown loggerhead, *Caretta caretta gigas* Deraniyagala, 1933. Reports, unsupported by material, but thought probably to be this species (or this species and the green turtle ?) comprise: (4–7) four individuals stranded at Studland Bay (Mr. G. Wainwright, about September 1951); (8) one swimming near Stanley (Mr. M. Hardy, 1951); (9) one stranded at Port Davey (Mr. C. Clayton, February or March, 1940); (10) one stranded near the mouth of the Arthur River (Mr. Bailey, date unknown); (11) one stranded at Currie, King Island (Mr. R. Clarke, 1951).

A paper dealing directly with the records enumerated above will appear in Vol. 90 of the *Papers and Proceedings of the Royal Society of Tasmania*; and it is hoped a further study of some of the problems raised by an examination of the material will later be published elsewhere.

Extraneous X-Ray Diffraction Patterns from Algal Flagella

WE should like to sound a warning that might save other workers in this new and difficult field from some of the troubles that have beset our own investigations. Our aim has been to obtain X-ray diffraction diagrams of oriented preparations of the flagella of algae, sperm, etc., of a standard comparable with those already obtained with bacterial flagella[1], and it was in fact believed that an encouraging advance towards this end had been achieved a few years ago[2]. Now, however, it has become apparent that it is much easier to discover diagrams of metabolic by-products and various other artefacts than of the flagella substance proper.

For example, flagella prepared from *Polytoma* grown in yeast/acetate/'Bacto-tryptone'/distilled water give a clean though non-specific protein diagram (diffuse, disoriented 'side-chain' and 'backbone' reflexions); but if tap water is used instead—and Leeds water is quite soft—then the protein diagram is lost in a strong pattern of an apatite type, to judge by its resemblance to patterns given by bone and dentine. The effect was finally tracked down to the intervention not of tap water alone but of tap water plus 'Bacto-tryptone'; but it was found that the pattern was given also by the lighter, more flocculent fraction of the precipitate formed when a distilled-water solution of 'Bacto-tryptone' was treated with $0{\cdot}1\ M$ ammonia. In the electron microscope this precipitate seemed amorphous, but electron micrographs of the flagella which gave the apatite-type X-ray pattern showed them to be crusted over with hexagonal-looking platelets—built up more slowly, of course, and under the conditions generated by the growing flagella. These conditions are known to bring the *p*H up to about 9, but evidently some contribution from the tap water is involved too.

Probably these results mean nothing more than that growing organisms produce things other than themselves, and that one must therefore watch with especial care in pioneer X-ray studies of this kind; but they could conceivably be pointing to something much more significant, for the artefact here is a by-product of organisms growing on constituents which include 'Bacto-tryptone', a pancreatic digest of casein; and it may be that the 'bone-like' nature of the pattern really is an expression of a remote relationship with large-scale biological apatite formation in multicellular creatures.

In any event, a more immediately important consequence has been the realization that it must have been 'Bacto-tryptone', too, that was ultimately responsible for the X-ray pattern we thought[2] came from the actual flagella of *Polytoma*, etc. It is clear now that this pattern was not authentic, but was of a metabolic by-product trapped in, or adhering to, the flagellar structure. Because of the difficulty of reproducing exactly the conditions and materials of the earlier experiments it is not certain exactly how, but the fact remains that a roughly similar pattern is given by fresh 'Bacto-tryptone', and a very similar pattern by what is left when the supernatant from an algal culture has been evaporated to dryness.

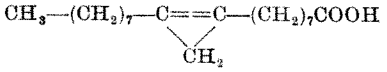
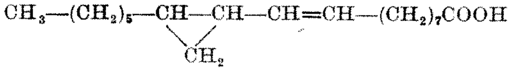
Sterculic Acid and its Halphen Reaction

THE structure of sterculic acid has recently been confirmed in this laboratory[1] as (I), proposed by Nunn[2], rather than as (II), suggested by Verma, Nath and Aggarwal[3].



$$CH_3—(CH_2)_7—C{=}C—(CH_2)_7COOH \quad \text{(I)}$$



$$CH_3—(CH_2)_5—CH—CH—CH{=}CH—(CH_2)_7COOH \quad \text{(II)}$$

This investigation revealed a band at $5{\cdot}35\mu$ in the spectrum of fresh sterculic acid, which is believed to be characteristic of a *cyclo*propene group. A strong band was also present at 9·92μ, as reported by other workers[3,4]. The latter band has been assigned by Verma *et al.*[3] to the *cyclo*propane group conjugated with a C=C double bond as in (II), by analogy with the absorption reported for this group at 9·9μ by Van Volkenburgh *et al.*[5] from the spectrum of vinyl*cyclo*propane vapour. A more accurate value for this band would seem to be that of Slabey[6] at 9·77μ, since it was obtained from a considerably better resolved spectrum of the same substance taken in solution.

Five other similarly conjugated *cyclo*propyl alkenes also have bands at 9·77–9·79μ, while the corresponding alkanes absorb at 9·82 or 9·83μ[7]. These values are all in close agreement with that found for dihydrosterculic acid at 9·80μ. However, the shift in wavelength of the *cyclo*propane group resulting from conjugation does not support structure (II) for sterculic acid; this shift, which was noted in one instance by Dijkstra and Duin[4], seems to be generally smaller than, and in the opposite direction to, that found in the transition from dihydrosterculic to sterculic acid.

Verma *et al.*[3] have stated that the Halphen reaction which is given by many seed oils is possibly due to some component of the non-saponifiable matter present in the oil. However, the reaction is given by fresh sterculic acid as well as by *Sterculia foetida* oil. Recently, too, the positive test obtained with cotton-seed oil has been attributed by Gunstone[8] to the presence of very small amounts of an acid with a *cyclo*propene ring; and Shenstone and Vickery[9] have found on testing the oils of two *Malva* sp. that the Halphen reaction is given invariably by the saponifiable fraction, and is due to an unsaturated acid present to about 3 per cent of the total mixed fatty acids. This acid, like sterculic acid, shows a prominent band at 9·92μ. It seems probable that the positive test found with so many other seed oils is also due to acids similar to these, present perhaps in small amounts only, for the test is very sensitive.

The addition of sulphur and amyl alcohol does not appear to be essential for the Halphen test. A solution of sterculic acid in distilled carbon disulphide, which was left for several weeks at room temperature, was already slightly orange on the day after its preparation, and quite a bright orange-red after four weeks. The reaction taking place was definitely associated with the presence of the *cyclo*propene ring in the sterculic acid: no colour was given by the polymerized acid, in which this ring had been destroyed[1], and the bands at 5·35μ and 9·92μ disappeared progressively from the spectrum of the sterculic acid as the colour of the solution intensified. Simultaneously a new band seemed to appear gradually (it was somewhat obscured by the heavy carbon disulphide absorption starting here) near 6·15μ; this is in the C=C double bond region of the spectrum, and suggests that, as with the polymerization[1], the reaction involved an opening of the ring across the single bonds. Numerous other spectral changes were also observed, the most remarkable being the rapid appearance of a strong band at 4·88μ, which increased in intensity for several days but later decreased again. This spectral region is normally very empty, and no mention was found in the literature of a likely group absorbing here, even though the band was very strong and sharp. The absorption has been tentatively assigned to the double bond in the grouping $-\mathrm{S}-\overset{|}{\mathrm{C}}=\mathrm{S}$, which is first formed by reaction between the carbon disulphide and the *cyclo*propene ring, and afterwards polymerizes across the C=S double bond. Another unknown broad band appeared progressively at 12·95μ: this is probably an antisymmetric C—S stretching absorption, which would predominate over the symmetric vibration in the polymer because of the unusual alternation of several carbon and sulphur atoms.

The exact mechanism of this reaction has not yet been established; but further investigation is proceeding.

I wish to thank Dr. J. C. Smith for providing the various samples of acids for infra-red analysis and the Scientific and Research Department, ISCOR, Pretoria, for the use of its infra-red spectrophotometer. Constitution of Chaksine

In the course of investigations on the constitution of the quaternary base chaksine, $C_{11}H_{21}O_3N_3OH$, isolated from *Cassia absus*, Linn.[1], pyrolytic degradation of its iodide has been studied. On pyrolysis with silver or copper filings, at 310–320° C., in a nitrogen atmosphere it gave ammonia, carbon dioxide and an oily product of deep red colour and soluble in ether, with a strong caraway-like smell, in about 10 per cent yield. This product on boiling with 20 per cent methanolic potassium hydroxide for 12 hr. yielded an acid soluble in petrol-ether (60°–80° C.) (melting point, 116° C. dec.) and an oily phenolic fraction soluble in petrol-ether. On using electrolytic copper in place of silver or copper filings in this degradation, the resulting ether-soluble oily product gave on hydrolysis, under the conditions described above, no acid soluble in petroleum ether but a much larger yield of the acid melting at 195° C. (dec.), which was identified as phthalic acid, finally through its anhydride. Accounting as it does for 8 out of 11 or possibly 12 carbon atoms of chaksine[1], this finding marks a significant stage in the elucidation of its constitution.

Full details of this work and other findings relating to investigations on the constitution of chaksine are being communicated elsewhere.

Absorption Spectra of Free PH_2 and PD Radicals

ALTHOUGH a large number of diatomic free radical spectra are known[1], very few spectra of polyatomic free radicals have been positively identified. The spectra are of interest since they are a potential source of information concerning the electronic states of these radicals and their dissociation energies, the vibrational and rotational constants of these states and their bond-lengths and bond-angles. The only polyatomic free-radical spectrum for which a vibrational and rotational analysis has been carried out is that of HCO [2] (and DCO), although partial analyses have been given for NH_2 [3,4], CF_2 [5,6], C_3 [7,8], SiC_2 [9], HS_2 [10], and a number of larger radicals, for example, CH_3O [11].

One powerful method for obtaining the spectra of free radicals in absorption utilizes the method of flash photolysis for the production of the free radicals, the White system of mirrors for obtaining long absorption paths, and a spectrograph of high resolving power for detecting fine absorption lines[2]. To obtain the best spectra, the maximum possible energy should be discharged through the photolysis flash tube in a time comparable to the life-time of the radical. In the 'microsecond' flash photolysis apparatus at Ottawa, ~ 1,000 joules of energy (40 μF., 7,000 V.) are discharged through the photolysis flash tube in 10–20 microseconds. The absorption spectrum is recorded by a second flash tube through which ~ 100 joules of energy (2 μF., 10,000 V.) are discharged, causing a continuum to be emitted for 3–5 microseconds.

The spectrum of PH_2 was observed during the flash photolysis of phosphine at ~ 5 mm. pressure. The half-life of the radicals under these conditions was ~ 50 microseconds. The length of the absorption path was 6 m. and the spectra were photographed in the second order of a 21-ft. grating spectrograph. Eleven bands were observed in the region 3600 to 5500 A. With fully deuterated phosphine (PD_3) prepared by the action of D_2O on PI_3, thirteen bands of PD_2 were observed in the same spectral region. Reproductions of the strongest PH_2 and PD_2 bands are given in Fig. 1.

The spectra are very complex, and as yet no rotational analysis has been carried out. The most characteristic feature is the clustering of groups of strong lines, probably Q branches, at regular intervals along the spectrum. The long wave-length edge of these strong groups has been used for the purposes of vibrational analysis; the vacuum wave numbers are given in Table 1. It is seen that the bands form regular progressions, the vibrational spacing varying from 887 to 976 cm.$^{-1}$ for PH_2 and from 626 to 690 cm.$^{-1}$ for PD_2.

Table 1. VACUUM WAVE NUMBERS AND ASSIGNMENTS OF PH_2 AND PD_2 BANDS

v_2'	PH_2		PD_2	
	ν_{vac}	ΔG	ν_{vac}	ΔG
0	18,271·8	951·3	18,271·6	690·3
1	19,223·1	937·6	18,961·9	684·5
2	20,160·7	928·7	19,646·4	676·2
3	21,089·4	915·5	20,322·6	673·2
4	22,004·9	901·6	20,995·8	665·9
5	22,906·5	888·9	21,661·7	657·2
6	23,795·4	887·4	22,318·9	647·5
7	24,682·8	905·1	22,966·4	636·6
8	25,587·9	938·6	23,603·0	627·3
9	26,526·5	976·4	24,230·3	626·5
10	27,502·9		24,856·8	634·0
11			25,490·8	655·4
12			26,146·2	

Units: cm.$^{-1}$

The assignment of these new bands to PH_2 and PD_2 is based on (1) the method of production of the bands by the photo-dissociation of PH_3 and PD_3, (2) the isotope shift when hydrogen is replaced by deuterium, (3) the rotational fine structure, which is too complex for diatomic PH, (4) the observed vibrational intervals, which are rather low to be assigned to PH stretching frequencies but which may be reasonably assigned to PH_2 and PD_2 deformation frequencies, and (5) the similarity of the spectrum to that known for NH_2.

The spectra may be interpreted as long progressions of the bending frequencies of PH_2 and PD_2 in the upper electronic state of the bands. Provisional assignments of the quantum number v_2' for the bending vibration are given in Table 1. It is interesting to note that for low vibrational quantum numbers, the vibrational intervals decrease with increasing v_2', while for higher vibrational quantum numbers ($v_2' > 7$ for PH_2 and $v_2' > 9$ for PD_2), the vibrational intervals increase with increasing v_2'. The energy at which this transition occurs is the same for PH_2 as for PD_2, indicating that the transition is a function of the potential energy curve of the upper electronic state. With large values of v_2', the amplitude of the bending vibration will be considerable, and at sufficiently high quantum numbers a stage will be reached when the hydrogen or deuterium atoms come into close contact during part of the vibration. This will cause appreciable repulsive forces to operate and will

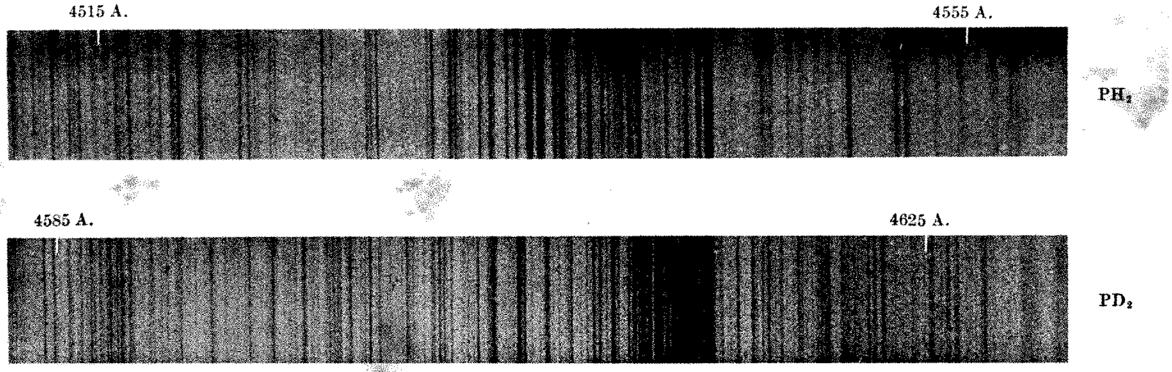

Fig. 1. Strongest absorption bands of PH_2 and PD_2 photographed in the second order of a 21-ft. grating spectrograph. The bands were observed during the flash photolysis of PH_3 and PD_3 at ~ 5 mm. mercury pressure. The length of the absorption path was 6 m.

result in an increase in the vibrational frequency. It is suggested that such repulsive forces are responsible for the observed increase in the vibrational frequencies of PH_2 and PD_2 at high vibrational quantum numbers.

Paper Chromatography of Pyrethrins and their Derivatives

Various methods have been described for the chromatographic separation of pyrethrin-type compounds. Alumina, silica and kieselguhr have been used as adsorbents for separation of 'pyrethrin I' from 'pyrethrin II' [1–3]. A separation of cinerin I from 'pyrethrin I', and 'cinerin II' from 'pyrethrin II', has almost certainly been achieved by Ward[2], using displacement chromatography on alumina. The 'pyrethrins' have also been separated by paper chromatography using alumina-impregnated paper[1] and 'Vaseline'-impregnated paper[4]. Hitherto, untreated paper has only been used with success for the separation of the 'pyrethrin' 2,4-dinitrophenylhydrazones, using light petroleum (b.p. 80°–100° C.) as solvent[1]. The present communication records a simple chromatographic system for separating pyrethrin-type compounds on untreated paper.

The main problems associated with partition chromatography of the 'pyrethrins' arise from their partition coefficients being very much in favour of the less polar phase of the commoner liquid–liquid systems. The applicability of methods which have been used in the steroid field[5,6], where similar problems are encountered, has now been investigated. It is found that an ascending solvent system of light petroleum (b.p. 80°–100° C.) saturated with methanol gives good results with 'pyrethrins' on Whatman No. 1 paper; a similar system has previously been used for œstrogen separations[7]. It is essential to equilibrate the papers overnight in an atmosphere of the two solvent phases.

The time necessary for pre-equilibration of the papers can be shortened to one hour by operating under reduced pressure, as suggested by Winteringham *et al.*[8]. Their apparatus has been modified (Fig. 1) so as to handle volatile two-phase systems, and also to permit the starting of the chromatogram, after a desired equilibration period, without breaking the vacuum. Two paper strips are hung on the horizontal portion of the tube *B* and kept apart by clipping the lower ends around a piece of glass rod. The ends should come to within ½ cm. of the solvent at *D*. The apparatus is evacuated through *A* to an extent governed by the boiling points of the solvent phases in *C* and *D*. After a suitable equilibration period, the chromatogram is started by running in sufficient of the appropriate solvent phase from a funnel fitted into the ground-glass joint on *A*. The liquid is discharged down the side of the vessel from the tube *B*, which is tapered to a jet. The starting line on which the samples are applied is drawn 6 cm. up the paper on account of the initial speed of solvent migration. The R_F values for a number of the compounds run at room temperature and atmospheric pressure were:

'Pyrethrin I'	0·85
'Pyrethrin II'	0·70
± *trans*-Chrysanthemic acid	0·54
± *cis*-Chrysanthemic acid	0·56
Chrysanthemum dicarboxylic acid	0–0·04
Methyl pyrethrate	0·73
α-DL-*trans*-Allethrin	0·82
Allethrolone	0·09

Considerable quantities of material remained on, or near, the origin with old samples of 'pyrethrins', due undoubtedly to the presence of polymerized products. Under reduced pressure, R_F values were higher than those obtained at atmospheric pressure; for example, 'pyrethrin I', 0·94; 'pyrethrin II', 0·87.

The compounds were detected by two methods:

(*a*) A method due to Winteringham *et al.*[9], which consists of dipping the papers in 0·1 per cent aqueous potassium permanganate, washing free of permanganate with water and partially drying. The papers are then treated with 0·5 per cent benzidine in acetone containing 5 per cent glacial acetic acid. The manganese dioxide formed in the presence of unsaturated compounds shows as intense blue zones. This method gives excellent results, although more permanent and intense colour resulted from using 0·5 per cent benzidine hydrochloride in aqueous solution.

(*b*) Use of the light petroleum–methanol system (both solvents being free from aromatics) allows the

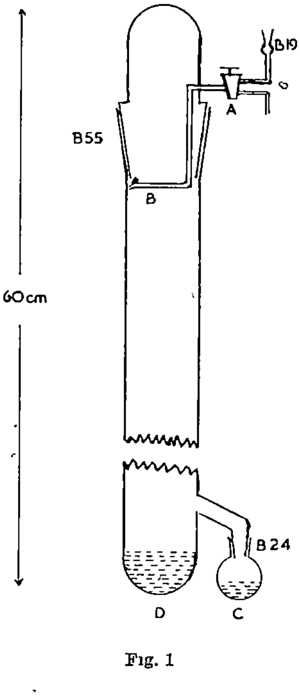

Fig. 1

technique of ultra-violet photography, which is widely used for derivatives of purine bases, to be applied. The pyrethrin-type compounds absorb strongly in the region of 230 mμ, due mainly to the *cyclo*-pentenolone grouping, and can be detected by exposure of the chromatogram, placed in contact with reflex document paper, to a Hanovia 'Chromatolite' ultra-violet lamp. The resulting photographs show the 'pyrethrins' as pale spots on a darker background. This technique, which cannot be applied to 'Vaseline'-impregnated paper, has the advantage that the separated compounds can afterwards be eluted unchanged from the paper. This method, however, is not so sensitive as method (a), a minimum of about 50 μgm. being needed; also, it does not detect chrysanthemic or pyrethric acids.

This work forms part of a research programme supported by the Pyrethrum Board and Department of Agriculture, Kenya, associated bodies in Tanganyika, and the Colonial Office, to which acknowledgment is made. I wish to thank Dr. L. Crombie, of the Imperial College, London, and Dr. M. Elliott, of Rothamsted Experimental Station, Harpenden, for gifts of samples, and also various colleagues in this Laboratory for their advice.

Occurrence of Nitropyrogallol Disulphate in Preparations of Nitrocatechol Sulphate

DURING an investigation of ox-liver sulphatase A [1,2] it became apparent that the substrate, nitrocatechol sulphate, was impure. As this was prepared by persulphate oxidation of p-nitrophenol[3,4] it seemed that a likely contaminant might be nitropyrogallol disulphate, formed by the oxidation of the phenol in both *ortho* positions.

When samples of nitrocatechol sulphate were submitted to paper electrophoresis at pH 4·2 the presence of two components was obvious, the yellow nitro compounds being readily seen after drying at 110°. In 4 hr. at a potential difference of 250 volts the major and minor components moved 4 cm. and 9 cm. respectively towards the cathode. The two bands were eluted with water and the phenols liberated from the sulphate esters by heating for 1 hr. at 100° in N hydrochloric acid. The phenol from the major component had an absorption spectrum in alkali identical with that of 4-nitrocatechol[5]. That of the minor component had a single sharp maximum and 430 mμ and was identical with the absorption spectrum of authentic 5-nitropyrogallol, kindly provided by Dr. T. S. Gardner. Partition chromatography on paper[6] confirmed the identity of the two phenols with 4-nitrocatechol and 5-nitropyrogallol. The major component of the substrate was therefore nitrocatechol sulphate.

The sulphate contents of samples of the acid hydrolysate of the minor component were determined by Dr. J. W. Minnis. The samples contained 318 μgm. nitropyrogallol and yielded 1,017 μgm. barium sulphate. These results were consistent with the view that the minor component of the substrate was nitropyrogallol disulphate.

Colorimetric determinations of the two components following electrophoretic separation showed that of three routine preparations of nitrocatechol sulphate two contained approximately 10 per cent, and one about 0·1 per cent of nitropyrogallol disulphate. A preparation by Dr. Brian Spencer contained approximately 2 per cent of the disulphate. The effect of nitropyrogallol disulphate on the kinetics of nitrocatechol sulphate hydrolysis by sulphatase A is under investigation; but electrophoretically purified samples of nitrocatechol sulphate exhibit the same anomalous kinetics as do unpurified preparations.

Modification of Glass Surfaces by p-Nitrobenzyl Bromide

IN the course of a study on the nature of the surface hydroxyl group of silicate glasses, it has been found that glass surfaces become permanently hydrophobic after being treated for 1 hr. with a dry, 30 per cent toluene solution of p-nitrobenzyl bromide at a temperature of 100° C. The effect was found with vitreous silica, borosilicate glasses and glasses of other composition. The most pronounced results were obtained with glass surfaces which had been freshly cleaved under distilled water and vacuum-dried before treatment with the above solution. The treated surfaces remained hydrophobic after prolonged exposure to common organic solvents and water.

In order to obtain more information on the nature of the surface modification and especially in order to distinguish between chemical reaction and adsorption, comparative studies on glass surfaces treated with p-nitrobenzyl bromide and glass surfaces treated with aqueous solutions of the quaternary ammonium compound cetyl-pyridinium hydrochloride were made. The two types of surfaces were affected by prolonged exposure to distilled water in distinctly different ways. The progress of the reaction between the surface and the water was followed by periodic measurements of the contact angle. A special apparatus was designed to measure the contact angles while the glass was continuously exposed to a stream of freshly redistilled water. The reproducibility of the measured contact angles was within 2 deg.

The hydrophobicity of a glass surface treated with *p*-nitrobenzyl bromide decreases slightly during the initial period of exposure, reaching a terminal value after sixty hours. After the terminal value is reached, no further decrease of hydrophobicity is observed. The hydrophobicity of the glass treated with cetylpyridinium hydrochloride, however, which is initially higher than that of glass treated with *p*-nitrobenzyl bromide, decreases continuously upon exposure to the distilled water, and the wettability of the surface approaches that of untreated glass surfaces.

The stability of the reaction product suggests the presence of an organic surface derivative of the glass, rather than an ion-exchange or adsorption layer, as is known to be the case with glass surfaces treated with quaternary ammonium compounds. The slight initial decline of the hydrophobicity of the glass surfaces treated with *p*-nitrobenzyl bromide at the beginning of the extraction is most likely to be due to the removal of adsorbed, unreacted *p*-nitrobenzyl bromide or other organic matter. It is unlikely to be caused by deposited layers of decomposition products of the *p*-nitrobenzyl bromide, for thin layers of this kind would gradually disappear upon extraction and thick layers would give a constant high value of hydrophobicity without any initial decrease. Experiments are under way to test this assumption.

The fact that in a further series of experiments no degree of hydrophobicity could be obtained by treating glass surfaces with *p*-nitrotoluene supports the view that the reactivity of the *p*-nitrobenzyl bromide depends on its —CH_2Br group and not the nitro-group. Further, it is significant that glass surfaces which were prepared under conditions expected to yield the largest number of hydroxyl groups per unit surface area yielded the most hydrophobic products after being treated with *p*-nitrobenzyl bromide.

On the basis of the above experiments, it is proposed that the mechanism of the reaction is the formation of a derivative of the surface hydroxyl of the glass according to the following reaction:

Regions of the Ionosphere responsible for Radio Star Scintillations

THERE is at present conflicting evidence as to the region of the ionosphere which is responsible for the scintillation of radio stars. Thus workers in the northern hemisphere[1,2] observing sources at fairly high angles of elevation, and also Mills and Thomas[3] in the southern hemisphere observing the Cygnus source at an altitude of 15°, have found a marked correlation between the occurrence of scintillations and of spread *F* echoes. On the other hand, Bolton *et al.*[4] at the same southern location as Mills, but observing sources within 10° of the horizon, found an equally marked correlation with sporadic *E*, but not with spread *F*.

We report here an analysis of some recent observations of scintillations[5], which appears to offer a solution to this problem. We find a correlation of night-time scintillations with spread *F* only, and of day-time scintillations with sporadic *E* only.

In the observations referred to, the source Cygnus *A* was observed from Dapto, New South Wales (lat. 34° 28·5′ S., long. 150° 47·5′ E.). The observations were restricted to ± 1 hr. from transit, when the altitude of the source is 15°. As reported earlier, the prevalence and intensity of scintillations vary markedly from day to day, but show two well-defined maxima, one when transit occurs near midday (December, summer), and one when transit occurs near midnight (June, winter) (Fig. 1). We are unable to determine whether these variations are diurnal or seasonal: for brevity, we shall refer to them as if they were diurnal.

In view of the occurrence of two such distinct maxima in the fluctuation index, the correlation between scintillations and ionospheric phenomena has been studied for day and night periods separately.

Day-time scintillations. Rays from Cygnus penetrate the *F* region (400-km. level) approximately 650 km. south-east of Townsville and 400 km. north-west of Brisbane, where routine ionospheric recorders are located. At no time during our day observations were spread *F* echoes reported from either of these stations.

For the *E* layer, the point of penetration lies 500 km. south-south-west of Brisbane and 500 km. north-north-east of Canberra, the nearest ionospheric recording stations. Table 1, which compares the sporadic *E* observed at these stations with the occurrence of scintillations, shows that the two are closely associated. There is a marked tendency for high fluctuation indices to occur when the critical frequency of sporadic *E* echoes is high. When the data are tested by either the χ^2 or the 'exact' test[6], it is found that the probability of the observed values occurring by chance if the two phenomena are independent is less than 1 in 10^4.

Because of the patchy nature of sporadic *E*, we have included in Table 1 only those days for which values of *fEs* (or *fE2s*) were available from both

Table 1. CORRELATION OF DAY-TIME FLUCTUATION INDICES WITH SPORADIC *E* AT BOTH BRISBANE AND CANBERRA. THE FIGURES GIVE THE NUMBER OF OBSERVING DAYS FALLING WITHIN THE DIFFERENT CATEGORIES

Fluctuation index	*fEs* (and *fE2s*) ≯ 5 Mc./s. at either Brisbane or Canberra	*fEs* (or *fE2s*) > 5 Mc./s. at both Brisbane and Canberra
0	15	3
1, 2 or 3	5	18

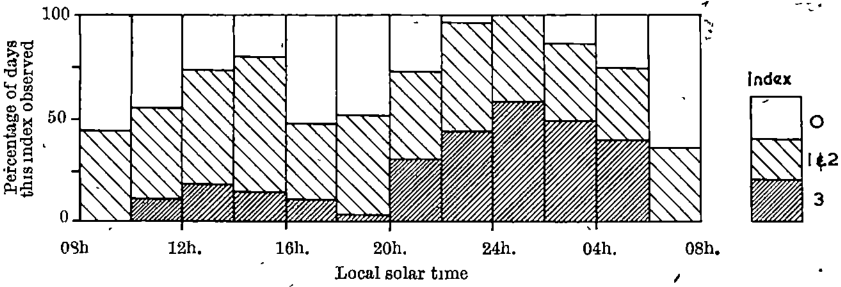

Fig. 1. Solar time variation of the fluctuation index. The index measures the prevalence and intensity of fluctuations on a scale increasing from 0 (no fluctuations) to 3 (very severe fluctuations). The observing days have been grouped according to the 2-hr. period in which transit occurred. Observations were made on 227 days during September 1952–February 1955

Brisbane and Canberra and for which either: (*a*) no value of *fEs* (or of *fE2s*) in excess of 5 Mc./s. was found at either of these stations during our observing period, or (*b*) a value of *fEs* (or *fE2s*) greater than 5 Mc./s. was recorded at both stations during our observations. The value 5 Mc./s. was chosen to divide the data into approximately equal parts: similar considerations decided the grouping of fluctuation indices used in Table 1.

Night-time scintillations. For night-time scintillations the correlation with spread *F* at Townsville is given in Table 2. In this case there is clearly a close association between the occurrence of high fluctuation indices and the appearance of spread *F*. According to either of the statistical tests mentioned, the probability of the figures occurring by chance alone is less than 1 in 10^6. There is a similar, but rather weaker, correlation with spread *F* at Brisbane.

Table 2. Correlation of Night-time Scintillations with the Occurrence of Spread *F* at Townsville

Fluctuation index	No spread *F*	Spread *F*
0 or 1	32	8
2 or 3	11	32

The results for sporadic *E* are given in Table 3, which shows no evidence of any correlation with night-time scintillations. Here 3 Mc./s. has been taken as the dividing value of *fEs*, again on the basis of separating the data into approximately equal parts. Other values were tried, and also other groupings of the fluctuation index, but none showed any evidence of a correlation between the two phenomena. The probability of figures such as those in Table 3 occurring by chance in uncorrelated data is about 0·6.

Table 3. Night-time Scintillations compared with Sporadic *E* at Brisbane and Canberra

Fluctuation index	*fEs* (and *fE2s*) $\ngtr$ 3 Mc./s. at either Brisbane or Canberra	*fEs* (or *fE2s*) > 3 Mc./s. at both Brisbane and Canberra
0 or 1	12	9
2 or 3	15	15

These results suggest that night-time scintillations arise in the *F*-layer and day-time scintillations in the *E*-layer. They are consistent with the observation that, at night-time only, there is a pronounced west-to-east component (some 80 m.sec.$^{-1}$) in the motion of the scintillation patterns across the ground[5]. Such a motion would be caused by the Earth's rotation if the irregularities were located at a height of about 500 km. and did not drift. It may also be noted that the current conception of sporadic *E* irregularities in terms of thin horizontal strata is in agreement with the fact that day-time scintillations have been reported only by workers observing at relatively low angles of incidence.

The ionospheric data for this analysis were taken from "Ionospheric Predictions, Series D", supplied by courtesy of the Ionospheric Prediction Service of the Australian Commonwealth Observatory.

The work described in this paper was carried out as part of the programme of the Division of Radiophysics of the Commonwealth Scientific and Industrial Research Organization, Australia.

Ultrasonic Absorption in Liquids from Thermal Steady States

In a recent communication[1] in *Nature*, we confirmed a new method developed in this Laboratory for the determination of ultrasonic absorption (α) in liquids. Subsequent work[2] has shown that the quantities of energy absorbed in cells, of small lengths, placed in the path of the sound beam with their incident faces occupying identical places, are in the proportion of their lengths. Utilizing this idea, we have evolved yet another technique for the measurement of α in liquids.

In this new method, a fairly strong beam of ultrasonic waves is produced in a liquid contained in a tank, surrounded by a constant-temperature bath. A small cylindrical double-walled brass cell fitted with thin mica windows to let the ultrasonic beam in and out of the cell is filled with the same liquid as that contained in the tank. The cell is placed co-axially in the path of the ultrasonic beam and, due to continuous passage of the ultrasonic beam through the liquid, the latter heats up, reaching a constant temperature when the heating of the liquid is balanced by the conduction loss. The temperature-difference in the steady state between the liquid in the cell and that in the tank is measured accurately by means of a sensitive thermocouple arrangement. If I_0 is the intensity of the ultrasonic beam on entering the first mica window of the cell and θ_1 the steady deflexion in the galvanometer, then:

$$I_0\{1 - \exp(-2\alpha l)\} = K\theta_1$$

where α is the absorption coefficient of the liquid, l the length of the cell and K is a constant.

Similarly, if θ_2 is the steady deflexion when the cell is placed at a distance x from the first position, we have :

$$I_0 \exp(-2\alpha x) \{1 - \exp(-2\alpha l)\} = K\theta_2$$

The absorption coefficient can then be calculated from these relations ; thus

$$\alpha = \frac{\ln \theta_1 - \ln \theta_2}{2x}$$

Necessary precautions were taken for the proper alignment of the cell, so that its movement was along the axis of the sound beam. Reflexion of the ultrasonic waves from the remote end of the large tank was also avoided.

This technique has been used for determining the absorption coefficient of ultrasonic waves at 5 Mc./s. in benzene, carbon tetrachloride, amyl acetate and xylene, thus covering a wide range of absorption coefficients (Table 1). The values are in good agreement with those obtained by other methods[3]. It is seen from the results that the method is capable of a high degree of accuracy, as the values can be reproduced to within ± 5 per cent of the mean value.

Table 1

Liquid	Temp. (° C.)	$\alpha/\nu^2 \times 10^{17}$ at 5 Mc./s.	Average	$\alpha/\nu^2 \times 10^{17}$ by other methods (ref. 3)
1. Benzene	19	849 766 820	812	900 at 22° C
2. Carbon tetrachloride	18	422 414 416	417	500 at 20° C.
3. Amyl acetate	19	183 177 178	179	166 at 29° C.
4. Xylene	18	95 92 91 96	94	78 at 25° C.

A detailed paper will be published elsewhere.

Unit-cell Dimensions and Space Group of 6-Mercaptopurine Monohydrate

Recent studies have directed attention to the possible chemotherapeutic activity of 6-mercaptopurine. The compound has been synthesized[1] and found to be a purine antagonist in *Lactobacillus casei*[2]. It acts as a moderate inhibitor on sarcoma 180 [3] and on some types of carcinoma[4]. A preliminary X-ray investigation of the substance was undertaken in view of its biochemical importance.

A sample of 6-mercaptopurine was given to us by Dr. Leonard Hamilton, of the Sloan-Kettering Institute for Cancer Research ; crystals were obtained from hot saturated aqueous solution upon slow cooling in a Dewar flask. Most of the crystals were yellow needles, elongated in the c-axis direction, with forms {0 0 1}, {1 1 0}, and sometimes {1 0 0} developed.

The crystals are monoclinic. Unit-cell dimensions were derived from rotation photographs and from zero-layer and first-layer Weissenberg photographs taken about the b- and c-axes with copper $K\alpha$ radiation. The crystallographic data obtained are listed below (together with their standard deviations).

a_0 = 15·29 ± 0·03 A. β = 102° 24′ ± 15′
b_0 = 7·76 ± 0·02 A. Density (by flotation) = 1·574 gm. cm.$^{-3}$
c_0 = 12·43 ± 0·04 A. Space group, $C_{2h}^{6} - C2/c$

Each unit cell contains eight molecules (calculated 8·07 for 6-mercaptopurine.1H_2O).

Because of the unfavourable dimensions of the unit cell, a complete determination of the structure of this crystal is not contemplated at present.

This investigation was aided by a grant from the National Foundation for Infantile Paralysis.

Magnetic Properties of Ferrichrome and Ferroverdin

Some time ago, Neilands and his associates isolated from the smut fungus, *Ustilago sphaerogena*, two pigments which he called ferrichrome[1] and ferrichrome *A* [2] because of their red colour and iron content (7·35 and 5·3 per cent respectively). Both ferrichromes have probably one iron atom per molecule, and are soluble in phosphate buffer in a presumably monomeric form[3]. They are easily decolorized by hydrosulphite and the reduced forms are autoxidizable[1,2]. The ferrichromes are also bleached by treatment with great excess of strong ferric ion-binding reagents, such as thenoyltrifluoracetone and versene. The red colour is restored on addition of ferric ions, or of ferrous ions in the presence of oxygen (Neilands, J. B., personal communication). There is thus very strong evidence that the iron in the oxidized ferrichromes is trivalent. Magnetic measurements were undertaken in order to confirm this and to elucidate the structure of the complexes.

The paramagnetic susceptibilities of the compounds and their reduced derivatives were determined in 0·1 M phosphate buffer, pH 6·9, at 20° C. No diamagnetic corrections were made and Curie's law was assumed to be valid in the calculation of the effective magnetic moments. The results are given in Table 1.

The values for the oxidized ferrichromes are in the region expected for trivalent iron with five unpaired electrons. The decrease in susceptibility of about 3,500 × 10^{-6} c.g.s. e.m.u. upon reduction is typical of a change from fully paramagnetic trivalent iron to fully paramagnetic divalent iron. If the decrease had been due to the disappearance of a free

Table 1

Compounds	χ (iron) (c.g.s. e.m.u. × 10^{-6})	μ_{eff} (Bohr magnetons)
Ferrichrome	13,630	5·68
,, + sodium dithionite	10,270	4·93
Ferrichrome *A*	13,860	5·73
,, + sodium dithionite	10,270	4·93

radical in the organic molecule, it would have been expected to be only about 1,300 × 10^{-6}.

The susceptibility values indicate further that only weak covalent bonds are involved around the iron, since all the 3*d* orbitals are occupied by unpaired electrons.

When 1 *M* fluoride was added to ferrichrome at *p*H 6·9, no change in spectral absorption or magnetic susceptibility could be observed. This behaviour contrasts with that of methæmoglobin or metmyoglobin, in which a co-ordinated water molecule is believed to be replaced by fluoride. It cannot be concluded, however, that water molecules or hydroxyl ions are not co-ordinated to the iron of ferrichrome.

Ferrichrome reduced by dithionite at *p*H 9·5 in presence of 0·1 *M* potassium cyanide was found to be completely diamagnetic. According to Neilands, aeration of such a sample does not restore the colour[3], and this has been confirmed. Addition of ferric ions, however, brought back the colour. The sample also gave the usual reactions of ferrocyanide upon acidification. The most likely explanation is that all the ferrous iron takes part in the formation of diamagnetic ferrocyanide; if a cyanide compound of ferrous ferrichrome exists to any extent in equilibrium with the ferrocyanide, it must be diamagnetic, have strong covalent bonds and be non-autoxidizable, but still be easily converted into ferrocyanide, properties that seem to be somewhat contradictory.

Recently, Chain *et al.* isolated from a new type of streptomycete another pigment of quite a different character[3]. Because of its iron content (9·3 per cent) and green colour they named it ferroverdin. It is insoluble in water but soluble in many organic solvents. When the pigment is reduced catalytically by hydrogen, twelve equivalents are used up and the green colour disappears and does not come back upon aeration[3]. The iron might thus be either divalent or trivalent; but the present investigation makes it possible to decide this question and also to draw some conclusions about the structure of the complex.

The magnetic susceptibility of the iron of ferroverdin was found to be 125 (± 160) × 10^{-6} c.g.s. e.m.u. in methanol solution and 20 (± 80) × 10^{-6} in ethylene glycol solution without any diamagnetic corrections being made. The preparation used contained only 6·6 per cent iron, and therefore the correction would not exceed 700 × 10^{-6} even if the partial specific volume of ferroverdin were equal to zero. A ferric compound with one unpaired electron should give a paramagnetic susceptibility of at least 1,300 × 10^{-6}. It may thus be concluded that the iron of ferroverdin is divalent and diamagnetic, and that two of the 3*d* orbitals are involved in covalent bonding. The complex is probably octahedral with d^2sp^3 bonds, and in this case, since ferroverdin contains no sulphur and only two nitrogen atoms per iron atom[3], at least four of the six chelating groups have oxygen or carbon co-ordinated to the iron by covalent bonds.

Ferroverdin in glycol solution reacted with hydrosulphite upon gentle heating. The colour turned brownish and the susceptibility increased to 9,500 × 10^{-6}. This implies that the covalent bonds are weakened or released under these conditions.

I am indebted to Dr. J. B. Neilands for the ferrichrome samples, to Prof. E. B. Chain for a sample of ferroverdin, and to Prof. H. Theorell for his interest in the work.

Internally Coated Cathodes

RECENT publications[1] have indicated that internally coated cathodes would be useful as sources of annular, high current-density electron beams in millimetre wave-length klystrons. For this application their behaviour in magnetic confining fields and their life are important. To study these factors, the cathode shown in Fig. 1 was used; in the first set of experiments, cathodes were made from 'O' nickel and coated with a standard triple-carbonate mixture. Cathode temperatures were measured with 0·005 in. diameter platinum–platinum 13 per cent rhodium thermocouples.

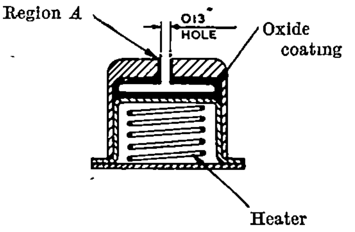

Fig 1. Geometry of an internally coated cathode

Fig. 2 shows current-voltage properties of the cathode, some of which have already been reported[2]. The current, which after a rapid initial rise increases linearly with voltage, is greater than the space-charge-limited current obtainable from a conventional cathode of the same area, and no evidence of saturation has been found up to fields of 50 kV./cm. Abnormally high cathode temperatures are required, however, to obtain high current-density beams. When immersion magnetic fields are applied, the form of the characteristic is unaltered, but the current obtainable at a given voltage and temperature decreases linearly with field; the maximum observed decrease was about 20 per cent at 3,800 gauss. Characteristics were studied over the ranges of current and temperature shown in Fig. 2 using d.c. voltages, and pulsed voltages of 1 m.sec. duration with duty cycles from 0·1 to 0·002; identical results were obtained.

At values of magnetic field and current used (less than 2,000 gauss, 10 m.amp., 6 kV.) the beam is annular, though cross-section studies[3] show that the peripheral distribution of current is not uniform. The

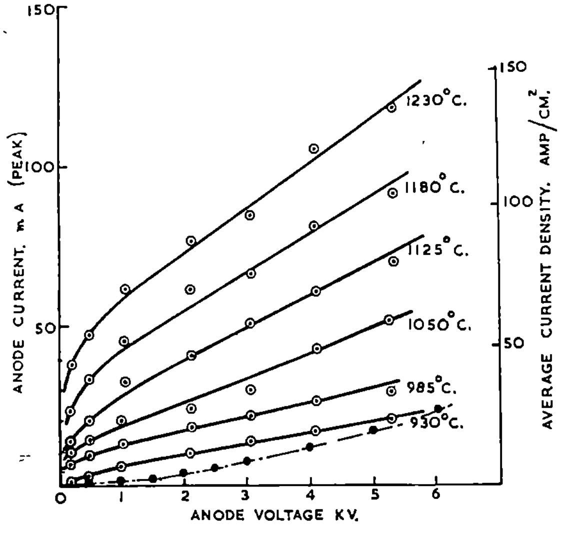

Fig. 2. Current-voltage characteristics of an internally coated cathode, with zero magnetic field: ———, experimental curves; — — ·, space-charge-limited current for an 'equivalent' diode

annular characteristic becomes less pronounced at higher values of magnetic field and current.

At 900° C., lives of 1,000 hr. were obtained at 5 amp./cm.² (assuming uniform emission over the aperture). At higher temperatures, lives were impractically short, for example, 10 hr. at 1,100° C., and were independent of the current-density drawn (5 amp./cm.² to 50 amp./cm.²). Examination of valves opened after testing showed that a layer of nickel had formed over the edges of the coating (region *A* in Fig. 1), at points where this lay slightly below the metal surface.

It has been suggested[1] that emission arises mainly from coating at the edges of the aperture. The present investigations support this in that (1) covering the coating near the aperture significantly reduces the emission, (2) the beam is annular at low currents, and (3) strong immersion fields cause only slight reductions in current. An explanation for the magnitude of the observed currents may also be given. Beam cross-section studies with small plane cathodes have shown that currents considerably greater than the space-charge-limited values may be obtained. With a 0·050-in. diameter cathode at 900° C. the current-density in an annulus 0·006 in. wide near the edge was about six times the space-charge-limited value. Thus edge effects can predominate in the internally coated cathode, because the width of the emitting area is generally small (0·002 in.); hence currents much in excess of the space-charge-limited values might be expected.

This communication is published by permission of the Admiralty.

Irreversibility and Mechanics

Prof. K. R. Popper has recently pointed out the error in the belief that " 'classical' mechanics . . . can describe physical processes only in so far as they are reversible in time"[1]. He cites the spreading of water waves resulting from a dropped stone as an example of a 'classical' process which is irreversible. This example is, however, not altogether convincing, since it is not obvious that a reversed set of water waves cannot be set up by a system of generators, coherently operating on the periphery of the water wave system; also, the propagation of water waves is in any event irreversible by virtue of being a dissipative process, while Popper's argument was for irreversibility of the waves on other grounds.

Morpurgo, Radicati and Touschek have discussed[2] time reversal, using the following definition. Let $\mathbf{r}$ be the position vector of a particle and $\dot{\mathbf{r}}$ its velocity; the property of time symmetry, or invariance under time reversal, requires that if equations of motion lead in a time interval t from a state $\mathbf{r}_1$, $\dot{\mathbf{r}}_1$ to a state $\mathbf{r}_2$, $\dot{\mathbf{r}}_2$, then in the same interval they also lead from $\mathbf{r}_2$, $-\dot{\mathbf{r}}_2$ to $\mathbf{r}_1$, $-\dot{\mathbf{r}}_1$. Using this definition as a criterion for path reversibility, we find that a clear example of lack of reversibility in mechanics is provided by certain solutions of the equation of Newton's second law.

We may write the law in the simple one-dimensional form,

$$F = m\ddot{x} \tag{1}$$

where F is a force in the x direction and m is a mass. Equation (1) is time reversible in the sense that it is the same with the use of either two positive or two negative differential increments of time. Further, (1) is reversible in that if it is integrated with an F that is a function of x, the path obtained after a velocity reversal is the reverse of the original path, as required by our adopted definition of path reversibility. Thus, with a gravitational force which is an $F(x)$, we have path reversibility. If, however, F is a function of t, one does not obtain such reversibility in the solution of (1), as will now be shown.

We take m to be a constant, and write $F(t)/m$ as $a(t)$, so that (1) becomes $a(t) = \dot{x}$. A first integration gives

$$\dot{x} = \int_0^t a(t)\mathrm{d}t + \dot{x}_i \tag{2}$$

where $\dot{x}_i$ is velocity at $t = 0$ and $\dot{x}$ is velocity at t. A second integration gives:

$$x_f = \int_0^{t_f}\left[\int_0^t a(t)\mathrm{d}t + \dot{x}_i\right]\mathrm{d}t + x_i, \tag{3}$$

where $x = x_i$ at $t = 0$ and $x = x_f$ at $t = t_f$. For the reversed motion, indicated by primed symbols, a first integration gives $\dot{x}' = \int_0^t a(t)\mathrm{d}t + \dot{x}'_i$. We integrate through the same time interval t_f as before, but with $\dot{x}_i' = -\dot{x}_f$ at $t = 0$, where $\dot{x}_f$ is the final velocity of the previous motion. A second integration, after replacement of $\dot{x}_i'$ by $-\dot{x}_f$ as determined from (2), gives:

$$x'_f = \int_0^{t_f}\left[\int_0^t a(t)\mathrm{d}t - \int_0^{t_f} a(t)\mathrm{d}t - \dot{x}_i\right]\mathrm{d}t + x'_i. \tag{4}$$

Since x'_i is equal to x_f, we may substitute x_f as given by (3) for x'_i in (4). We then find for the final position, x'_f, in the reversed motion:

$$x'_f = \int_0^{t_f}\left[2\int_0^t a(t)\mathrm{d}t - \int_0^{t_f} a(t)\mathrm{d}t\right]\mathrm{d}t + x_i. \qquad (5)$$

It is apparent from (5) that, with an $F(t)$, solutions of (1) will not in general have the property of path reversibility; for the reversed motion does not, after time t_f, give $x'_f = x_i$. (A sinusoidal force, $F = b\sin\omega t$, provides a simple example of an $F(t)$.) In the special case that $a(t)$ is a constant, (5) reduces to $x'_f = x_i$; and, as noted, we do have path reversibility when (1) is solved with an $F(x)$. It appears that motions under various kinds of physical forces must be individually examined for their reversibility properties.

RICHARD SCHLEGEL

Department of Physics,
Michigan State University,
East Lansing, Michigan.

[1] Popper, K. R., *Nature*, **177**, 538 (1956).

[2] Morpurgo, G., Radicati, L. A., and Touschek, B. F., *Nuovo Cimento*, **12**, 677 (1954).

MR. R. SCHLEGEL's definition of temporal reversibility, which he credits to Morpurgo, Radicati and Touschek, is clearly too narrow. It has to be extended, so as to cover a (conservative) physical system rather than one single particle.

Take the case of a planetary system: if we reverse the velocity of one of the planets, at the time t_f and at the position x_f, the planet will clearly not reverse its path precisely: upon reaching, at the time $t_f + \Delta t$, the position $x_f + \Delta x$, which we may assume to be very nearly the same as the one which it occupied at $t_f - \Delta t$, the planet will not be acted upon by the same force which acted upon it at the time $t_f - \Delta t$. If, however, we reverse the motions of all the planets in the system, then the force will be the same; the system is reversible.

This shows that the problem of reversibility or irreversibility arises only with respect to a (conservative) physical system. It is obvious that, in a classical model, the motion of one planet or of one particle cannot be reversed.

Mr. Schlegel proposes to consider the reversibility of the motion of one particle under the action of a time-dependent force. There are, clearly, two cases to be considered. In the first case, the temporal changes of the force in question are explicable (that is, deducible, or predictable) in terms of the changes within the system; in classical mechanics, in terms of the changing positions of the various particles. Classical mechanics is reversible in the sense that if the velocity vectors of all particles are reversed, the temporal and positional changes of the forces (but not their directions, of course) are also reversed, and all the particles return on the paths on which they came. In the second case, the changes of the force in question are not explicable in terms of the changes in the system. In this case, the problem of reversibility, and of the 'arrow of time', does not arise: irreversibility is trivial, except under the assumption that the temporal changes of the force are also reversed.

Mr. Schlegel operates with a changing force the changes of which he does not reverse. He therefore obtains the obvious result: the motion of his particle will not in general be reversible.

Concerning Mr. Schlegel's comments on my own communication, I wish to make four remarks.

(1) I have found since that nearly half a century ago, Einstein used a somewhat similar argument[1]. Had I known this, I would not have written my communication.

(2) The difference between Einstein's argument and mine is that I have pointed out (*a*) that the generators would have to be coherent, and (*b*) that the demand that the coherence of the generators should be explained, and the explanation incorporated into the model, must either be given up (which means accepting the process as irreversible) or it will lead to an infinite regress. Mr. Schlegel mentions coherence, but he does not appear to have fully appreciated my admittedly very brief sketch of the way in which we are led to an infinite regress, if we do not wish to accept the coherence of the generators as an ultimate and inexplicable conspiracy of causally unrelated conspirators.

(3) As to dissipating processes, there are two kinds of dissipation which do not always seem to be clearly distinguished. Dissipation in the form of increasing disorder (entropy increase) is one of them, and dissipation by expansion without increase of disorder is the other. For an increase of disorder, walls of some kind are essential: a sufficiently thin gas expanding in a 'vessel without walls' (that is, the universe) does not increase its disorder. In the absence of walls, collisions become rapidly extremely improbable, and the degree of order of the system begins to increase in time, in the sense that the fastest particles will all be found near the periphery of the expanding gas ball and the slowest particles near its centre. If this development is prevented by the insertion of 'walls' of some kind (the 'walls' may be gravitational fields preventing the escape of particles) then the disorder will increase.

(4) My earlier brief communication was merely an attempt to point out the untenability of the widespread, though surely not universal, belief that the 'arrow of time' is closely connected with, or dependent upon, the law that disorder (entropy) tends to increase. Beyond this, I did not attempt to cover the subject.

K. R. POPPER

University of London.

Application of Impedance Measurements to Corrosion Phenomena

IN connexion with a recent communication[1] it should be pointed out that the application of impedance measurements to corrosion phenomena is not new. Extensive measurements of the resistance and capacity of painted steel specimens have been carried out for a number of years[2] and have proved most useful in studying the breakdown of paint films.

In the course of this work, the possibility was raised of extending the method to other thin films such as anodic oxide films. The present work[1] demonstrates the usefulness of the method in the study of phenomena within oxide films formed during corrosion.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

MAP CURATOR AND LIBRARIAN (preferably with qualifications in geography and in librarianship) IN THE DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Sheffield (August 25).

LECTURER (with a good degree in physics, teaching and research or industrial experience, and preferably special qualifications in some branch of applied physics) IN PHYSICS—The Principal, Acton Technical College, High Street, Acton, London, W.3 (August 25).

PLANT PHYSIOLOGIST (with a good honours degree in botany or agricultural botany)—The Registrar, University College of Wales, Aberystwyth (August 25).

CHEMISTS (with a first- or second-class honours degree) at the North Thames Gas Board's Chemical By-Products Works, Beckton, East Ham, London, E.6, for research on problems in connexion with coal tar distillation, and the manufacture of phenols, naphthalene and bases—The Staff Controller, North Thames Gas Board, 30 Kensington Church Street, London, W.8, quoting Ref. 666/288 (August 27).

ASSISTANT IN ELECTRICAL ENGINEERING—The Secretary of the University Court, The University, Glasgow (August 31).

ASSISTANT LECTURER IN THE DEPARTMENT OF PHILOSOPHY—The Registrar, University College of Wales, Aberystwyth (August 31).

ASSISTANT LIBRARIAN (with some experience in a scientific or technical library) IN THE SCIENCE AND TECHNOLOGY SECTION of the University Library—The Librarian, The University, Edmund Street, Birmingham 3 (August 31).

DISTRICT (Forest) OFFICERS (with, or obtain in summer 1956, a university degree or diploma in forestry, or a postgraduate degree in a forestry subject)—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting Ref. No. 146/56/1 (August 31).

LECTURER IN THE DEPARTMENT OF METALLURGY to lecture in X-ray metallography and the thermodynamics of alloys—The Registrar, The University, Liverpool (August 31).

LECTURER IN ANIMAL HUSBANDRY AND PREVENTIVE MEDICINE at the University Veterinary School—The Secretary of the University Court, The University, Glasgow (August 31).

LECTURER (preferably with experience in tropical plant physiology) IN PLANT PHYSIOLOGY at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 31).

ASSISTANT PHYSICIST, Basic grade (with a good honours degree in physics and preferably experience in electronics and nuclear physics techniques) IN THE PHYSICS DEPARTMENT of the Sheffield National Centre for Radiotherapy—The Secretary, Sheffield Regional Hospital Board, "Broom Cross", Tree Root Walk, Sheffield 10 (September 1).

BIOCHEMIST (with an appropriate science degree of a university of Great Britain or associateship of the R.I.C.) for duties at the Harrogate and District General Hospital and Royal Bath Hospital—The Group Secretary, Harrogate and Ripon Hospital Management Committee, Hereford Lodge, Cornwall Road, Harrogate (September 1).

PRINCIPAL (graduate of a British university, with teaching and, if possible, some administrative and industrial experience) OF BRADFORD TECHNICAL COLLEGE—The Director of Education, Town Hall, Bradford (September 1).

RESEARCH FELLOW (with a good honours degree either in engineering, physics or mathematics, and preferably some practical experience) IN ENGINEERING—The Registrar, The University, Nottingham (September 1).

SENIOR LECTURER IN THE DEPARTMENT OF NATURAL PHILOSOPHY—The Secretary, The University, Edinburgh (September 1).

DEMONSTRATOR IN GEOLOGY—The Registrar, King's College, Newcastle-upon-Tyne (September 4).

LABORATORY ASSISTANT (preferably with laboratory experience) at Ealing Technical College—The Principal, Ealing Technical College, St. Mary's Road, Ealing, London, W.5, quoting "T.323.N" (September 10).

RESEARCH FELLOW or JUNIOR RESEARCH FELLOW (organic chemist with research experience, preferably on natural products) at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 10).

PHYSICIST or PHYSICAL CHEMIST (with an honours degree in physics and a good knowledge of instrumentation) to work in the new Research Department of Anæsthetics—The Secretary, Faculty of Anæsthetists, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2 (September 12).

UNIVERSITY DEMONSTRATOR (with an honours degree in pure science with organic chemistry and biochemistry as principal subjects) IN ANIMAL NUTRITION—The Secretary, School of Agriculture, The University, Cambridge (September 12).

SENIOR LECTURER (graduate in agriculture or pure science) in charge of an Agricultural Research Station to be established in the Forest Region of the Gold Coast (University College of the Gold Coast), for the study of soils and crop production—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 27).

HEAD OF THE DEPARTMENT OF PHYSIOLOGY; and a SENIOR PRINCIPAL SCIENTIFIC OFFICER IN THE EXPERIMENTAL PATHOLOGY DEPARTMENT—The Director, Institute of Animal Physiology, Babraham Hall, Babraham, Cambridge (November 15).

ASSISTANT PROFESSOR (with teaching experience and research interests in inorganic or physical chemistry) IN CHEMISTRY—Prof. C. A. McDowell, Department of Chemistry, University of British Columbia, Vancouver 8, B.C., Canada.

BOTANIST (with postgraduate research experience) for work on the seasonal accumulation, translocation and utilization of reserve materials in fruit trees, to extend the knowledge of tree growth, flowering and fruiting already being obtained by methods of growth analysis; and a BIOCHEMIST (with postgraduate research experience) for work on the metabolism of fruit plants—The Secretary, East Malling Research Station, near Maidstone, Kent.

CHEMICAL ENGINEER (with a degree in chemical engineering and research experience) at a research institute in Aberdeen for research on smell suppression in the manufacture of fish meal—The Herring Industry Board, 1 Glenfinlas Street, Edinburgh 3.

CHEMIST (with an honours degree in chemistry or agriculture with a strong chemical bias, followed by postgraduate training in soils work and general ecology) IN THE DEPARTMENT OF AGRICULTURE, Tanganyika, to work as a member of a team investigating soil fertility problems and surveying new development areas—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/20.

DEPUTY DIRECTOR (with good academic qualifications and record for research work, preferably experience of tropical tree crops, including cocoa, and the working of a research institute) OF THE WEST AFRICAN COCOA RESEARCH INSTITUTE, Gold Coast, to take charge of the research work and administration of the Institute's Sub-station at Ibadan, Nigeria—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/200/016.

LECTURER or ASSISTANT LECTURER (with a university degree in electrical engineering and practical experience in the electrical industry) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

LECTURER (with a good honours degree in science or horticulture and preferably some postgraduate research experience) in HORTICULTURAL SCIENCE—The Registrar, The University, Bristol 8.

LECTURERS IN AGRICULTURE—The Bursar, Royal Agricultural College, Cirencester.

METALLURGIST, CHEMIST or PHYSICIST (with a degree), IN THE INFORMATION DEPARTMENT, for work dealing with every aspect of the recording and transmission of information on the extraction, manufacture and uses of non-ferrous metals and their alloys—The Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

PHYSICAL CHEMIST, Principal or Senior Scientific Officer grade (with a first- or second-class honours degree in physical or inorganic chemistry, and an experienced physical chemist with a special interest in thermodynamics), to direct a team engaged in research relating to reactors—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1206/34.

RESEARCH CHEMICAL ENGINEER (with a first- or second-class honours degree in chemical engineering or in chemistry, a strong interest in applied physical chemistry problems, and preferably some research experience in chemical engineering or physical chemistry), to undertake investigations into the chemical and chemical engineering aspects of new processes under development in the atomic energy field—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1227/34.

RESEARCH WORKERS (with a first-class degree in engineering, physics or applied mathematics and several years research experience) IN THE MECHANICAL ENGINEERING DEPARTMENT, for research on combustion involving the solution of theoretical problems by network analogue, etc., and experiments on flames—Dr. D. B. Spalding, Imperial College of Science and Technology, London, S.W.7.

SENIOR and JUNIOR RESEARCH FELLOWS (Chemists and Physicists) IN THE DEPARTMENT OF GLASS TECHNOLOGY, to work on the problems of the glassy state—Prof. R. W. Douglas, Department of Glass Technology, The University, Sheffield 10.

SENIOR LABORATORY STEWARD (male or female, preferably with some general experience in a laboratory and G.C.E. in physics) IN THE PHYSICS LABORATORIES—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics and background experience in solid-state physics with at least three years postgraduate research experience, and preferably experience of spectrography or electronics) to investigate certain physical aspects of the detonation of solid high explosives and of the propagation of intense shock waves through solids and gases—The Senior Recruitment Office, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1228/34.

SENIOR SCIENTIFIC OFFICERS (with an honours degree or equivalent, and preferably some industrial and technical experience); and SCIENTIFIC OFFICERS (preferably with an honours degree or equivalent), for work which will include research into problems connected with the coking industry, the preparation of technical reports, and may involve participation in operational research in the provinces from time time—The Secretary, The British Coke Research Association, 74 Grosvenor Street, London, W.1.

PERMUTIT ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED, Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

Permutit Ion Exchange Materials — Made in Britain by British Labour

THE GRIFFIN THERMOSTATIC OVEN

FOR ALL-ROUND THERMAL EFFICIENCY

The Griffin Thermostatic Oven has been designed for use in Chemical, Metallurgical, Bacteriological and Pathological laboratories. It is ideal for all drying and sterilizing work.

Easy to clean and resistant to staining, the exterior has a durable cream finish, the interior being aluminium. The door and casing are heavily lagged and a combined thermometer support and rotatable ventilator is fitted in the roof.

Simple to operate, the base controls comprise an on/off switch, pilot lamp and sensitive slow-motion thermostat. A temperature gradient of ±1° C., over the range from about 5° C. above ambient to 300° C., is constantly maintained. No measurable temperature variations at any one point can be detected.

Low power consumption is achieved by the most careful design and disposition of the heating elements. The chamber space is 26 cm. by 36 cm. diameter... ... ... £54 0 0

LECTURES AND COURSES

CHELSEA POLYTECHNIC
MANRESA ROAD, S W.3
DEPARTMENT OF CHEMISTRY
SESSION 1956-57

A course of 20 postgraduate lectures on "Biochemistry" (to be arranged in four groups) will be given by Dr. E. M. Crook, M Sc , A.R.I.C., and Professor F. L. Warren, M A , D.Sc , on Mondays 7.15 to 8 30 p.m , during the period October 1, 1956, to March 18, 1957 The course is designed for students who possess a knowledge of chemistry to degree standard. Fee: £2 for whole course or 10s. for each group.

A leaflet giving details is obtainable from the Secretary.

CHELSEA POLYTECHNIC
(Provisionally designated College of Advanced Technology)

DEPARTMENT OF CHEMISTRY

SANDWICH COURSE IN CHEMISTRY

A Sandwich course in preparation for the examinations leading to Graduateship of the Royal Institute of Chemistry will commence in January, 1957. The course (works based) will be of four years' duration, and will involve six-months' study at College each year. The normal requirements for admission to the course will be successes at A Level (G.C.E), or comparable examinations, in chemistry together with physics and/or mathematics, and three suitable ordinary level subjects.

Inquiries from industrial firms, research organizations and government departments will be welcomed. Particulars from the Clerk to the Governors, Chelsea Polytechnic, Manresa Road, S.W.3.

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE
ACTON TECHNICAL COLLEGE
HIGH STREET, ACTON, W.3
HIGHER TECHNOLOGICAL COURSES, 1956-57

The following short courses will be held in the Department of Chemistry and Biology during the Autumn Term, 1956.

Radiochemistry: Twelve lectures on Wednesdays, commencing September 19, 1956, at 7.30 p m. Fee, £1. A special course on modern aspects of radiochemistry and its applications.

Recent Advances in the Chemistry of Oils, Fats and Waxes: Twelve lectures on Fridays, commencing September 12, 1956, at 7.30 p m. Fee, £1. Oils and Fats 10s.; Waxes 10s. The course will include six lectures in Oils and Fats and six in Waxes with special reference to modern technique.

Some Modern Aspects of Physical-Organic Chemistry: Six lectures on Thursdays, commencing November 1, 1956, at 7.30 p.m. Fee, 10s.

Laboratory Course in Chromatography and Ion Exchange: Short full-time Four-day course commencing September 4, 1956, at 10 a.m.

Laboratory Course on Oils, Fats and Waxes: One-year Part-time course on Fridays, commencing September 21, 1956, at 2 p m.

Plastics Technology, Materials and Processes: Short course of lectures on Tuesdays, commencing September 25, 1956. Suitable for Production and Design Engineers. Fee, 10s.

Lecturers will include Specialists from Industry and Research Associations

Further particulars and enrolment forms may be obtained from the Principal.

C. E. GURR, M.Sc , Ph.D.,
Secretary to the Education Committee.

THE POLYTECHNIC
309 REGENT STREET, W.1
DEPARTMENT OF MATHEMATICS AND PHYSICS

The following courses of lectures have been arranged starting in September, 1956 Each course of about 26 lectures.

(1) Some Techniques of Mathematical Physics: I, Vector and Tensor Calculus, on Tuesdays, 7 to 9 p.m.

(2) Some Techniques of Mathematical Physics: II, Integral Equations and Greens Functions, on Wednesdays, 7 to 9 p.m.

(3) Fluid Dynamics. Dynamics of Ideal Fluids and of Real Fluids, on Mondays, 6.30 to 9 p m.

Full particulars may be obtained on application to the Director of Education

UNIVERSITY OF MANCHESTER

The next session commences on Thursday, October 4, 1956.

OFFICIAL APPOINTMENTS

CITY OF BRADFORD EDUCATION COMMITTEE

In view of the fact that the Bradford Technical College has been designated provisionally as a College of Advanced Technology, it has been decided to re-advertise the vacant post of Principal The College includes the following Departments: Textiles, Chemistry and Dyeing. Civil, Mechanical and Electrical Engineering. Mathematics, Physics and Applied Optics, Biology, Pharmacy Commerce, Languages and Banking Over 5,000 students enrolled for the present session, including 465 full-time students. A considerable portion of the work is already recognized for the Advanced Technology rate of grant and an appreciable amount of Research Work is being carried out. The present salary scale—£1,950 by £50 to £2,200 per annum—is subject to review in the light of the new Burnham Award. The revised salary (by agreement with the Ministry of Education) will be commensurate with the proposed status of the College and the duties involved. Applicants should be graduates of a British university and should have had teaching and, if possible, some administrative and industrial experience. Applications received in response to previous advertisements will be considered unless the applicant wishes to withdraw.

Application forms (stamped addressed envelope) and particulars, may be obtained from the undersigned, to whom completed applications should be returned not later than September 1, 1956.

A. SPALDING,
Director of Education.

Town Hall,
Bradford, 1.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

Research workers required in Mechanical Engineering Department for research on combustion involving solution of theoretical problems by network analogue, etc., and experiments on flames. First-class degree in engineering, physics or applied mathematics and several years' research experience required. Salaries according to qualifications and age on scale similar to that for Scientific Civil Service

Applications, with qualifications and names of referees, to Dr. D. B. Spalding, Imperial College, S.W.7.

UNIVERSITY OF GLASGOW
SENIOR LECTURESHIP IN AGRICULTURAL CHEMISTRY

Applications are invited for a Senior Lectureship in Agricultural Chemistry. Salary scale £1,400 by £50 to £1,650. Initial salary according to experience and qualifications. F S.S.U. and family allowance benefits.

Applications (six copies), should be lodged, not later than September 15, 1956, with the undersigned, from whom further particulars may be obtained.

ROBT. T. HUTCHESON,
Secretary of University Court

THE ANTARCTIC DIVISION, OF THE DEPARTMENT of External Affairs, Canberra, invites applications for appointment to the post of Glaciologist with the 1957 expedition to Mawson, Australian Antarctic Territory. The appointee will be required to draw up a glaciological programme, procure equipment, personally carry out glaciological work at Mawson and prepare results for publication on return to Australia; also to assist with seismic ice-depth determinations. Applicants to have an appropriate university degree and produce evidence of aptitude to carry out the duties. Salary will be within the range £A.1,443 to £A.1,623 dependent on qualifications and experience plus cost of living allowance £A.24 per annum While absent from Australia on expedition, kitting and maintenance are provided free and a tax-free regional allowance of A 12s 6d. per day single man and A.17s. 6d. per day married man is payable in addition to salary Fares will be paid to Australia.—Applications, accompanied by a recent photograph and stating full name, place and date of birth, marital state, nationality, present employment, particulars of qualifications and experience, and of war service, if any, with the names and addresses of two persons willing to act as referees, should reach Senior External Affairs Representative, Australia House, Strand, London, W.C.2, not later than September 8, 1956.

COLCHESTER GROUP HOSPITA MANAGEMENT COMMITTEE

The whole-time post of Senior Biochemist the Colchester Group Hospitals is now vacant a applications are invited The successful applica will be required to work under the Area Pathol gist and to perform biochemical estimations a examinations for the hospitals and clinics of t group. Main duties will be at Essex County H pital, Colchester. Further details may be obtain from the Consultant Pathologist at that hospit Salary according to Whitley Council Scale (£9 by £40 to £1,230 per annum).

Applications, together with the names of th referees, should be forwarded to the Group S retary, Colchester H.M.C., 14 Pope's La Colchester, Essex.

RESEARCH CHEMISTS
required by
THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON, BERKSHIRE

Principal/Senior Scientific Officer (Ref. C154/34). To work in a team engaged on fundamental research work on radioactive materials. Applicants should hold a first- or second-class honours degree in chemistry with some research experience. They should possess a sound knowledge of modern analytical techniques as applied to radioactive substances. Experience in the use of high vacuum equipment would be an advantage. Salary: Principal Scientific Officer, £1,390 to £1,980 per annum; Senior Scientific Officer, £1,155 to £1,355 per annum.

Scientific Officer (Ref. 1232/34). To carry out applied research in the field of inorganic chemistry in a range of interesting new materials Candidates should hold a first- or second-class honours degree in physical or inorganic chemistry and have experience in applied research Salary will be assessed according to age, qualifications and experience, within the scale £615 to £1,065 per annum.

At present the rates for women are slightly lower.

Contributory superannuation scheme. Married officers now living outside the Establishment's transport area will be eligible for housing on one of the Authority's estates; alternatively, assistance towards legal expenses incurred in house purchase may be available, until housed a lodging allowance may be payable.

Requests for application forms, by postcard, to Senior Recruitment Officer at the above address. Please quote appropriate reference number.

ROYAL COLLEGE OF SURGEO OF ENGLAND

Physicist or Physical Chemist required to wo in the new Research Department of Anaesthet Applicants must have an honours degree physics and a good knowledge of instrumentati The post will provide good opportunities for th interested in biological and medical applicatio of physics. Starting salary in the range £8 to £1,100 per annum, according to experience

Applications, in writing (two copies), giving tails of qualifications and experience, toget with the names of two referees, should be s to Mr. W. F. Davis, Secretary, Faculty of Ana thetists, Royal College of Surgeons, Lincol Inn Fields, London, W C.2, by September 1956.

BRITISH IRON AND STEEL RESEARCH ASSOCIATION

Graduate required for the South Wales Labo tories of the above Association in Swansea develop new processes for continuously apply protective coatings to steel strip at high spee Candidates should have an honours degree physics, metallurgy or electrical engineering, a should have had some research experience. T post is a progressive one and offers a good o portunity for the man with ability and initiativ The Laboratories are pleasantly situated in Singl ton Park on the Gower Coast side of Swanse Starting salary up to £900 per annum, accordi to age, qualifications and experience. Post superannuated under the F.S.S.U.

Written applications only, quoting M.W.C. to Personnel Officer, B.I.S R.A., 11 Park La London, W.1.

SHORTAGE OF MATHEMATICS AND SCIENCE TEACHERS

THE Dunsheath Committee which considered the shortage of mathematics and science teachers concentrated upon the more advanced studies of future specialists; it paid little attention to their earlier education and the scientific education of the remainder of the population. Realizing that this might well be the core of this difficult problem, the Association of Teachers in Colleges and Departments of Education set up a committee to examine the problem and to report. Its report, which has been prepared by five people connected with the work of training colleges, is probably more alarming in its revelations than anything so far published on a question where no real solutions have yet been proposed*.

The report surveys the total output of trained teachers in England and Wales for one whole year and analyses the courses taken by those training college students who have made any substantial study of mathematics or of a science during their training. It also gives information about the mathematical and scientific attainments of all students on entry to the colleges, and discusses the staffing of the colleges.

The information received shows clearly that very few girls both able and willing to specialize in mathematics or in the physical sciences are attracted to teaching as a career, and that the qualifications of men teachers who have taken mathematics or science degrees are, on the average, very much inferior to those of men in training who have specialized in other subjects. There are insufficient women to maintain present staffing requirements, and the shortage of mathematics and science staffs in girls' schools is rapidly becoming worse. There are insufficient men to provide any expansion of staff to teach the very much larger age-groups of children that will be entering secondary schools in 1957 and subsequent years or to provide trained teachers able to contribute to the expanding facilities for scientific and technological education which the Government has recently promised. The value of the report lies both in its novel effort to examine the basic reasons why students are not becoming teachers of mathematics and science in numbers and quality to suit the national interest, and in the sincerity and humility with which it criticizes those defects in the training colleges and departments of education that help to aggravate an apparently intractable problem.

The Committee is unanimous that the failure to attract sufficient properly qualified recruits is a reflexion of the status and prestige of teaching as a profession relative to other careers open to men and women with some scientific ability.

Although nearly half the women students entering training colleges have passed in mathematics at their General Certificate examination, the attitude of a large number of them to the subject is undesirable; dislike and even hostility to mathematics and arithmetic is characteristic of many. This attitude is often established before entry to a grammar school. Students who as children, were inadequately taught at school do not willingly take up a serious study of mathematics in training colleges; and, unless this attitude is modified during training, they leave college and take with them into schools their negative attitude towards arithmetic and have to teach with this personal background.

The key to the situation lies in the supply of trained mathematics and science graduates from universities, a supply which has remained consistently low for some years; the supply is low because teaching has virtually ceased to attract either mathematics or science honours graduates. Once present shortages have been made good, the scales of the teaching situation would be turned by the additional recruitment each year of about fifty men and fifty women honours mathematicians—two of each sex from each university in Great Britain—with rather fewer physicists and chemists and a few extra biologists; about 250 extra recruits are required each year out of the total of more than 6,000 science and technological graduates. For lack of this number the whole future of the nation's supply of scientists and technologists is being jeopardized.

Some help could be given by those training colleges which provide concurrent degree and certificate courses; the Committee urges that they should be given financial and other inducements not only to continue this work but also to extend it to provide as many graduate scientists and mathematicians as possible.

For the great majority of student teachers, basic courses in mathematics and science will provide the only opportunity in training colleges of presenting to them afresh the subjects they will teach in schools but which are not their main subject of study. This work can only be successfully accomplished if adequate time can be devoted to it, and, in view of the considerable amount of remedial work and re-education in mathematics and arithmetic which now appears necessary, particularly with a majority of women students, the Committee considers that the promised extension of the period of training from two to three years will alone provide sufficient time for these courses to be planned on an adequate scale. With the expectation that this reform will be effected within about the next four years, it is recommended that a national committee be set up to investigate resources and collate ideas preparatory to the revision of syllabuses by institutes of education. By the time the three-year course is introduced, it is essential that all training college staffs should include experienced graduate lecturers competent to teach mathematics and science students.

---

* The Supply of Mathematics and Science Teachers: a Survey of Students in Training. By a Sub-Committee of the Association of Teachers in Colleges and Departments of Education. Pp. vi+56. (London: Methuen and Co., Ltd., 1956. Published for the Association of Teachers in Colleges and Departments of Education.) 3s. 6d. net.

The short-term problem calls for immediate measures to be taken. One-third of the women's training colleges are without a member of staff who has graduate qualifications in mathematics, and in a majority of colleges no mathematician or scientist is among those members of the staff whose special responsibility is pedagogy and the principles and practice of education. Until this staffing shortage is remedied, only a proportion of students will be able to benefit from other steps which may be taken.

At the present time a number of colleges are experimenting with new courses and combinations of courses, and here the Association of Teachers in Colleges and Departments of Education could do much to co-ordinate developments. Third-year supplementary courses both in mathematics and science, including some extending over three years, are planned to begin next year in some colleges. These courses should be widely advertised, and more teachers should be encouraged to enrol for them.

The largest age-group will not be entering secondary schools until 1958, and it should not prove impossible during the next two years for local authorities to second a number of experienced teachers to take supplementary courses designed to enable them to become competent mathematics or science specialists for secondary schools; this would help to ease the burden.

Of the subjects usually taught in schools, mathematics is the only one selected by fewer than about 10 per cent of training college students. For mathematics less than one woman teacher in twenty-five at present qualifying will have any substantial knowledge of this key subject of the curriculum. This is scarcely enough to provide one medium-sized school in three with a teacher whose main interest can be expected to lie in the teaching of mathematics and arithmetic. The Committee feels that "It is pertinent to ask whether it is in harmony with the needs of the second half of the twentieth century that, in the training of teachers, art and craft should be studied by nine times as many women as those who study mathematics, geography three times as many as mathematics and history more than all the sciences and mathematics put together".

The report suggests that science and mathematics lecturers should be given opportunities to see entrants at the earliest possible occasion, either immediately the students enter college or on the occasion of the interview when students are selected for admission. Headmistresses of girls' grammar schools could also give active encouragement to a number of their pupils during their final year at school.

A further difficulty is that few books of any sort are available which open up new vistas and present mathematics afresh to training college students who are only accustomed to the standard grammar-school books. There is a great need for someone who loves mathematics and is in close touch with the needs of training college students to write attractive text-books calculated to woo women students from their apparent distaste of everything mathematical.

If training colleges are not to be prevented from fulfilling their vital task of producing trained teachers of mathematics and science, more highly qualified men and women must be attracted to them as lecturers. It is most desirable that the training of students be entrusted to well-qualified mathematicians and scientists who are thoroughly experienced teachers; but the present Pelham scales of training college salaries cannot compete with the inducements which may be offered, under the Burnham scales, to a sixth-form graduate teacher with whom a school does not wish to part, and who would be very difficult to replace. For some years to come the training colleges will have to provide all the mathematics and science teachers for secondary modern schools and also supplement the supply of graduate teachers to the grammar schools. It is essential that training colleges be provided with the qualified and experienced staff necessary to make this much-needed contribution of trained teachers of mathematics and science. As long as those women's colleges which do offer main courses in mathematics have only classes as frustratingly small as is often the case, many graduate teachers will prefer to remain in grammar schools where their classes are larger and include potential university scholars; not until teachers have served in a training college can they fully appreciate the interest of its varied work.

The shortage of science lecturers and the lack of balance between the subjects they profess will take some time to correct. As an immediate measure, it is recommended that each institute of education should survey the number and qualifications of science lecturers within its own area, that principals and governing bodies of training colleges should be informed of the balance and distribution of science lecturing resources and that area training organizations should encourage some measure of collective responsibility for the provision of balanced facilities for the various scientific disciplines.

Whatever particular solutions are eventually reached, it is essential to recognize the existence of an emergency and to be prepared to take bold steps to meet it. Any solution which introduces new ideas may well lead to new forms of partnership between the universities and training colleges of Britain, which may later prove of value in other respects.

THE CIVIL SERVICE

The Civil Service

Some Human Aspects. By Frank Dunnill. Pp. 226. (London: George Allen and Unwin, Ltd., 1956.) 18*s*. net.

FOR the scientific worker, as such, the interest of this book is limited by the exclusion from its scope of the Scientific Civil Service, though the picture Mr. Frank Dunnill gives of the recruitment, training, methods and working conditions of the Civil Service in general should be useful to any scientist who is brought into contact with the Civil

Service, whether he is himself a member of the Scientific Civil Service or not. Moreover, Mr. Dunnill discusses with understanding and a certain dry humour the relations between the Civil servant and Parliament and between the departments and the organized public, as well as with the individual, in a way that should assist those outside the Service to understand its ways and its point of view and at the same time help those within to avoid actions or attitudes that create friction. He has a keen sense of the human problems involved, and his criticism is usually constructive and well directed, though his suggestion for a series of advisory departmental committees, empowered to ask questions on the department's relations with the public and to secure authoritative explanations of the advantages or inherent impossibility of particular procedures, may be debatable as a means of securing the continuous re-examination of practices and the removal of misunderstandings without hindering administration.

The book is of value for its discussion of the factors which are changing the Service to-day and its relations with the public it serves, particularly of the effect of social change on the administrative and executive branches. Mr. Dunnill is convinced that any effective reform of the Civil Service must come from within and not in response to pressure from without—as a result of its executive and administrative officers putting their minds on the work that is being done and eliminating practices no longer useful or relevant. What is lacking, he remarks, of those few thousand higher executive officers in charge of many thousands of junior officers is not, for the most part, the mental capacity to reorganize and deploy their juniors more economically and more intelligently, but training, encouragement and the conviction that management is a primary part of their job and one to which they should actively apply themselves. Real economy in man-power and woman-power comes not at some sudden point from outside but as a result of careful forethought and study of the intelligent and efficient employment and development of human beings, having regard also to the important responsibilities which they may later have to bear outside as well inside the Service.

Mr. Dunnill's major hopes for the future appear to rest in the fact that "the younger higher executive officers, promoted since the Second World War, belong for the most part to the best crop of middle-grade officers the Service has had for a very long time". The great danger is that before they reach positions of high responsibility they lose some of their force and energy, enlightenment and sympathy. If this is to be avoided, it will be mainly through what happens within rather than without the Service, though such books as this could contribute to the real understanding of the Civil Service which will enhance its prestige and standing in the nation and limit the amount of ill-informed criticism and often ill-judged financial cuts. The basic problems, however, are human ones, and Mr. Dunnill's main conclusion is that the key to full efficiency in the Civil Service lies in the intelligent use of the people in it. He indicates very clearly the factors, both external and internal, which can help to that end, and scientists and technologists will note with interest his comments about the professional groups, though he seems to overlook the influence which a freer passage from such groups into the administrative branch, particularly of the scientific officers, might exert.

Although it has much general interest, Mr. Dunnill's book is perhaps primarily for those within or in direct contact with the Civil Service. It should help to a fuller understanding on the part of those outside and stimulate fresh thought and initiative within. Unfortunately, not only is there no bibliography, but even where Mr. Dunnill quotes he does not trouble to cite his source. The value of the book would also have been enhanced had an index been included.

R. Brightman

BIBLIOTHECA WALLERIANA

Bibliotheca Walleriana

The Books Illustrating the History of Medicine and Science collected by Dr. Erik Waller and bequeathed to the Library of the Royal University of Uppsala. Compiled by Hans Sallander. (Acta Bibliothecae R. Universitatis Upsaliensis, Vols. 8–9.) Vol. 1: Pp. xii+471+plates 1–48. Vol. 2: Pp. viii+494+plates 49–55. (Stockholm: Almqvist and Wiksell, 1955.) 200 Sw. Kr. the two volumes.

No catalogue exists that contains all works ever published on either early science or early medicine, nor is it likely that one will ever be compiled, still less published. Moreover, the needs of those who require accurate bibliographical descriptions of the books that such a catalogue would contain are even less adequately provided for. In consequence, potential users of this hypothetical catalogue—students of the history of science and medicine, librarians, bibliographers, book collectors and antiquarian booksellers—owe a lasting debt to the great book collectors who have made specialized collections of which catalogues have been published; or who have prepared bibliographies of the works of great scientists of the past. As examples, one may mention Prof. J. F. Fulton's bibliographical studies, particularly his bibliography of the works of Robert Boyle; John Ferguson's "Bibliotheca Chemica"; Dr. G. L. Keynes's bibliography of the works of John Ray; and, in the field of medicine, the latter's bibliographical account of the publications of William Harvey; and Sir William Osler's "Bibliotheca Osleriana". To these must now be added the "Bibliotheca Walleriana".

Dr. Erik Waller was born at Önum in the province of Västergötland, in Sweden, on November 29, 1875. He graduated M.B. at Upsala in 1900, and continued his studies at the Karolinska Institutet in Stockholm until 1905. Afterwards he practised as a surgeon in various parts of Sweden until 1909, when he returned to his native province. Here he became surgeon in the Lidkoping Hospital, where he remained until his retirement. He was librarian to the Swedish Medical Association in Stockholm during 1940–46; and in 1951 he returned to Lidköping, where he died on January 28, 1955.

It would be interesting to know whether great book-lovers such as Dr. Waller are born with some inherent propensity to collect; or whether their interest in the historical development of a special field of knowledge is the driving force that leads them on to amass a library of books on their subject and perhaps to write about it. Dr. Waller must have acquired, in the course of his lifetime, an exceptionally wide knowledge of the development of medical science; but he appears to have written next to nothing on the subject. In his case, therefore, the first explanation is possibly the more probable, though the mere labour of getting together such a collection can scarcely have left a practising surgeon much time for writing. In any event, Dr. Waller became active as a collector when quite young, in the early 1900's. Originally, manuscripts and autograph letters were his main interest, and he amassed nearly twenty thousand letters ranging in date from the early sixteenth century to the beginning of the nineteenth century. Many of these were written by, or addressed to, men famous in the history of medicine; but they also covered a wider field, including almost all aspects of modern cultural life. This collection, which included medieval codices and scientific manuscripts as well as letters, was acquired for the Royal University Library of Upsala by purchase.

Dr. Waller's main achievement, however, was his collection of old medical books. This, like his collection of autograph letters and manuscripts, he extended to include works on many other branches of knowledge more or less directly related to medicine, including general natural science, specific natural and physical sciences, the history of the natural sciences and of medicine, the biography of medical men and scientists, and the bibliography of medicine and science; and there is even a section in his "Bibliotheca" dealing with the literature pertaining to the study of manuscripts and autograph letters.

Dr. Waller was always generous in making his collections accessible for study by scholars, and it was with this intention that he decided in 1950 to present the whole of his collection of books to the University Library at Upsala, where it is now permanently available for this purpose. The University is indeed fortunate in having become the custodian of such an outstanding collection. It far exceeds in size and importance those made by Sir William Osler and Dr. Harvey Cushing, for example. There are 150 incunabula, more than a hundred editions of Hippocrates, thirty-six editions of the works of Vesalius, including a copy of his doctoral dissertation; forty-three editions of Ambroise Paré's books; and what is claimed to be the world's largest collection of the writings of William Harvey, totalling fifty different editions. These examples emphasize the size of the collection; but other important writers are also well represented, and there are a great many extremely rare books on a variety of medical topics, some of them unique. A number of the books in the collection are of especial interest because of the notes by former owners which they contain. Among them are books formerly owned by William Harvey and Vesalius.

The main part of the library, the old medical books, together with the incunabula, are catalogued in Volume 1, which has 10,721 entries. These are listed alphabetically by author, excepting only the incunabula, which are catalogued separately. There are also forty-eight plates in this volume, mainly reproductions of the title pages of old medical books. Volume 2 is divided into several alphabets, according to subject, and contains all books other than the old medical works. It brings the total number of entries up to 20,428. These are numbered consecutively throughout the two volumes, irrespective of subject, so that it is possible to refer to any one book in the collection by its number alone. Volume 2 contains seven plates, bringing the total up to fifty-five. Finally, there is an exhaustive index of names and subjects, with many cross-references, extending to ninety-four pages. This has been modelled on the index of the "Bibliotheca Osleriana", and it adds immensely to the value of the catalogue as a work of reference.

The bibliographical descriptions of individual entries in the catalogue are given concisely, as follows: title (in full, unless exceptionally long); edition; place and date of publication; format; pagination; illustrations; other relevant information. The names of former owners are also indicated in some cases. Printers' names have been given for all works earlier than 1700. The catalogue does not include the several thousand reprints that form part of the Waller collection, except for a few considered especially important by Dr. Waller himself.

The "Bibliotheca Walleriana" forms Volumes 8 and 9 of the *Acta Bibliothecae R. Universitatis Upsaliensis*, and 1,600 copies only have been printed. It has been prepared by Mr. Hans Sallander, of the University Library, Upsala; and all notes and other remarks additional to the actual book titles are in English. It is a reference work of outstanding importance which, no doubt, many large reference libraries, particularly those used by medical and scientific students, will wish to acquire. It will also appeal to many book collectors, and, if its price seems rather high, this should be considered in relation to the vast amount of information it contains, and the immense care that has evidently gone into its production. It forms a worthy monument to the memory of Dr. Erik Waller, through whose labours and generosity this great collection is now available for consultation by all interested students.

V. A. Eyles

CHEMICAL AND BIOLOGICAL ACTION OF RADIATIONS

Actions Chimiques et Biologiques des Radiations
Collection dirigée par M. Haïssinsky. Première Série. 1: Aspects Physiques de la Radiobiologie. Par L. H. Gray. 2: Chimie des Radiations des Solutions Aqueuses. Aspects Actuels des Résultats Expérimentaux. Par M. Lefort. 3: Modern Trends in Radiation-Biochemistry. By W. M. Dale. Pp. viii+254. (Paris: Masson et Cie, 1955.) 2800 francs.

As the title indicates, this is the first volume of a series which, as pointed out by the editor, Dr. M. Haïssinsky, is to be a comprehensive collection of monographs dealing with all aspects of this field.

During recent years, the chemical and the biological action of radiations have become subjects of considerable theoretical and practical importance, and it has also become apparent that these two fields are, in many ways, closely related to each other. Until comparatively recently, the basic concepts in radiobiology were almost entirely founded on the 'target theory', which, although capable of providing some kind of formal representation of certain aspects of radiobiology, did not seem to advance this subject any further. It was not until the knowledge of the chemical action of ionizing radiations was put on a new theoretical and experimental basis that a deeper understanding of the fundamentals of radiobiology was possible.

The chemical effects are dealt with in Part 2 by Dr. M. Lefort, who discusses what has now become known as the radiation chemistry of aqueous solutions.

Part 1, by Dr. L. H. Gray, represents something between text-book material and a monograph. The discussion is based essentially on the earlier concepts of D. E. Lea; there is no reference to the more recent work of Kramers which, from the physical point of view, is rather fundamental for the action of ionizing radiations in liquid systems. In Part 1, and particularly in Part 3, by Dr. W. M. Dale, there is probably too great a tendency to apply results obtained on very dilute aqueous solutions to biological systems.

It would, perhaps, not have been inappropriate to give rather more prominence to the work of Hollaender and Latarjet on the possible relationship between radiobiology and photobiology. It is clear that, in general, the behaviour of biological systems towards radiation does not depend so much on the energy of the incident primary particle or quantum but rather on the energy-levels of the particular compounds which are involved. Thus, even in the case of high-energy radiations, electronic levels of only a few electron volts may ultimately be of great importance for the chemical and related biological effects.

Part 3 deals mainly with the chemical action of ionizing radiations on certain selected organic compounds (for example, thiourea) in aqueous solution. There is little discussion of the actual biochemical effects produced by ionizing radiations, a subject which has become known, to a large extent, through the work of Hevesy and Forssberg; only one very brief reference to Hevesy's work has been given, and this dates back to 1945.

In spite of certain shortcomings, this volume contains much stimulating information and a useful collection of references, and one is indebted to the authors for having undertaken a difficult and somewhat unrewarding task. The specialist concerned with one aspect of the wide and diverse field of the chemical and biological action of radiations often feels the need for comprehensive accounts of the many other fields of work closely related to his own. This new series, when complete, should go a long way towards fulfilling this need. A special word of praise and encouragement is due to Dr. Haïssinsky, who is to be wished every success in the further development of this collection of monographs.

J. Weiss

HANDBOOK OF REACTOR PHYSICS

Reactor Handbook: Physics

Prepared by the United States Atomic Energy Commission. (Selected Reference Material on Atomic Energy.) Pp. xvi+790. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 90*s*.

This handbook is one volume in a series sponsored by the United States Atomic Energy Commission with the avowed intention of providing a condensed source of reliable data and reference information in the field of reactors. The volume is devoted to reactor physics and radiation shielding, the latter subject occupying approximately a quarter of the book.

The first two chapters are devoted to experimental methods and nuclear physics. The former refers to neutron sources and detectors and, in outline, to methods of measurement of fundamental and integral nuclear and reactor data. The latter is primarily concerned with an extensive compilation of the properties of nuclei in tabular and graphical form.

The remainder of the section on reactor physics is devoted to the kinetic theory of neutrons and reactor statics and dynamics. The kinetic theory of neutrons discusses some of the approximations which are commonly used in the analytical solution of Boltzmann's equation. This treatment is rather sketchy for the mathematician, but the principles are discussed and references to more detailed papers are given. The application of these approximations to steady-state reactor problems is given, but attention is concentrated on homogeneous reactors. No theoretical treatment of heterogeneous reactors is given, but the results of various integral measurements, including experiments to determine critical factors, are prefaced by a statement of simple formulæ for computing the characteristics of an infinite lattice reactor. Many results are given, but it is disappointing that no attempt is made to correlate these results with theoretical estimates made in different ways. The chapter on reactor dynamics contains a useful discussion, with numerical examples, of the effect of changes in reactivity on the neutron intensity. Consideration is also given to the criteria for stability in a power-producing reactor, taking into account the problem of heat dissipation and the power and temperature reactivity coefficient. Typical calculations for control rods complete this chapter.

The section of the book on shielding contains chapters dealing with sources of neutrons and gamma-rays in a reactor, radiation tolerances, neutron and gamma attenuation and heating including the effect of geometry and ducts, optimum dimensions of shields and a tabulation of general properties of shielding materials. As in the previous section, the tabulation of data is extensive and in general very useful. The number of experimental results from shielding experiments which are quoted is rather small, and little attempt is made to recommend procedures.

The authors of the handbook are clearly aware of the limitations imposed on the contents and on its presentation by the rigid target date for the production of this edition. As a consequence, however, some of the information given is difficult to digest, and the reader must be experienced in the field and prepared to work hard in order to extract the information really required from such a handbook. An outstanding exception to this is the tabulation of many useful general and nuclear properties of materials used in reactors. Modifications to any future editions, which would make this handbook of outstanding value both to newcomers and to the experts in this field, are a general unifying introduction, a constructive criticism of theories and experiments and their limitations, and, in particular, a recommendation of specific methods and data which correlate with experiment for specific problems.

The production of this handbook was obviously a formidable task, and the authors are to be congratulated on producing a volume of this kind in the time available. Nevertheless, as the members of the review board have indicated in their preface, "the ultimate success of the handbook will depend a great deal upon the refinements in subject-matter and presentation which will come about in subsequent revisions".

Peter W. Mummery

Chemical Engineering

By J. M. Coulson and J. F. Richardson. Vol. 2: Unit Operations. Pp. xvi+387–975+65 plates. (London: Pergamon Press, Ltd., 1955.) 60*s*. net.

THE second volume of "Chemical Engineering" completes the treatment of unit operations of which the more fundamental fluid flow and mass transfer were the main theme of Vol. 1 (*Nature*, 175, 228 (1955)). Flow of fluids past particles includes filtration, sedimentation, and gas cleaning; mass transfer across an interface includes distillation, absorption, liquid-liquid extraction and leaching. Finally we have evaporation, crystallization, drying, size reduction of solids and mixing. Physical reactions only are considered owing to a paucity of rigorous methods of solution where chemical reactions are involved; similarly such subjects as automatic control and the design of reactors have been specifically excluded.

As with the first volume, each chapter contains a list of the more important references and a list of symbols and is very well illustrated with line diagrams, sectional drawings and photographs of equipment used in chemical engineering operations. An appendix contains 121 problems of university degree standard.

The more fundamental treatment in Vol. 1 is utilized as required in the second volume, as in the application of mass transfer in Chapter 7 to absorption in Chapter 19. The treatment throughout is mathematical with a slight tendency to underplay the physical conditions underlying the various operations. Thus, in so far as bubbles and drops are concerned, whereas Stokes's law is thoroughly considered and Hadamard's allowance for internal circulation is discussed, no mention is made of the limited range of internal circulation for which Bond and Newton postulated an interfacial tension factor. This is a very minor note of criticism since a good balance has been achieved between the various sections and the essential unity of the mass transfer and of this operation is well brought out.

These two volumes are outstanding in this field and present a formidable challenge to all previous chemical engineering text-books. F. H. GARNER

Selecta Hermann Weyl

(Herausgegeben zu seinem siebzigsten Geburtstag von der Eidgenössischen Technischen Hochschule in Zürich und vom Institute for Advanced Study in Princeton.) Pp. 592. (Basel und Stuttgart: Birkhäuser Verlag, 1956.) 48.90 francs; 48.90 D.M.

THIS selection from the published papers of the late Hermann Weyl was prepared by a committee of his friends: Eckmann, Hopf and Plancherel in Zurich, and Morse, von Neumann and Selberg in Princeton. Their purpose was to choose from Weyl's works whatever was of permanent and historical importance, within the limits set by the size of a single volume. Weyl himself helped them with advice and approved their choice. He also added illuminating comments to some of the earlier papers, explaining how he came to write them and how his feelings about them changed in the light of later history. The volume was prepared for Weyl's seventieth birthday, and an advance copy was handed to him at the official celebration in Zurich. The public edition, appearing now after his death, will serve as an altogether fitting memorial to him.

Nineteen papers are reprinted, covering all Weyl's major interests in physics and mathematics. There is a bibliography of those which were left out. The well-known classical papers are all here. The reviewer started reading, not the famous papers, but those he had never heard of before. The same procedure is recommended to others. Every paper is then a surprise, filled with fresh insights and unexpected beauty.

Tragic Safari

By Albert Mahuzier. (Translated by Alec Brown.) Pp. 144+16 plates. (London: Elek Books, Ltd., 1956.) 16*s*. net.

THIS book is an account of a trip to French Equatorial Africa to make colour films of wild animals, especially at night by flashlight. All the plans went wrong, and the white hunter was mauled by a lion and bled to death for lack of proper 'first aid'. The author has unusual ideas about filming animals in the field: he apparently aims at getting his pictures after the white hunter has mortally wounded the victims, or after he has caught a leopard in a 'panther trap', an enormous gin anchored to a log of wood. Some of the illustrations of animals show living, tame, captives; the rest are portraits of corpses. The translation is poor and full of gallicisms; the translator has not bothered to find the English equivalents of many of the French names of animals so that the text speaks of the guib, bubale, cephalophus, potamocherus, and so on. The value of the book may be judged by the caption beneath a photograph of the body of a warthog; it informs the reader that the picture shows a "dead rhinoceros".

The blurb on the jacket says "It is Mahuzier himself who gives us 'the loveliest girl of Maripanda', her beater raised in one hand, while the fingers of the other caress the taut tom-tom skin to produce the intoxicating double-rhythm". Reference to the picture, however, shows "the belle of Maribanda" pounding mealies in a wooden mortar with her free hand on the edge to prevent the contents spilling as she reduces them to meal. Further comment is needless. L. HARRISON MATTHEWS

Advances in Catalysis and Related Subjects

Edited by W. G. Frankenburg, E. K. Rideal and V. I. Komarewsky. Vol. 7, 1955. Pp. xi+362. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 9 dollars; 72*s*.

THIS volume contains a series of monographs having as their general theme the nature of the chemical bonds formed between catalysts and adsorbed substrates, special attention being paid to electron-transfer processes involved in chemisorption on the surface of metals and semiconductors. Summaries are given of newer techniques for the study of chemisorption, including the use of the field emission microscope, by means of which it becomes possible to see images of individual molecules and to obtain valuable information on their constitution and configuration in the adsorbed state. In this way, a stage has been reached at which changes in state on adsorption can be followed by experimental observation.

Good reviews are also given of the theory of chemisorption and of modern high-vacuum working with clean surfaces. In the case of adsorption and catalysis on metals, it is perhaps a little unfortunate from the point of view of practical catalysis that this necessary provision of a clean adsorbing surface involves the use mainly of tungsten, which can easily be cleaned by high-temperature desorption but which is not a good catalyst for reactions such as general catalytic hydrogenation. However, this is unavoidable; and the results obtained with tungsten can in many cases, although with some presumption, be applied to good general catalysts such as platinum.

The book is to be recommended. There is, in parts, some overlap in the matter presented in individual sections, but this is incidental and indeed conducive to clarity.

E. B. MAXTED

The Dorset Coast

A Geological Guide. By G. M. Davies. Second edition. Pp. vii+128+7 plates. (London: Adam and Charles Black, Ltd., 1956.) 9*s.* 6*d.* net.

THE appearance of a second edition of "The Dorset Coast" will be welcomed alike by the amateur and professional student; to quote from the preface to the first edition, "it enables the lone hunter to find his quarry without having to refer to the scattered literature on the subject". The format of the book remains unchanged, a feature being the division of the coast into western, central and eastern sections, with numerous day excursions based on Bridport, Weymouth and Swanage, respectively. The author's extensive experience of conducting geological expeditions, as well as the breadth of his knowledge, are placed at the reader's disposal, so that the resulting guide-book presents a fascinating picture of a coast-line where "the beginner sees folds and faults as clearly recognizable as in text-book diagrams, while the advanced student finds many problems still inviting investigation".

The plates have been carefully chosen and are well produced; the frontispiece to this new edition contains striking views of Lulworth Cove and Stair Hole. The maps and diagrams supplement the text and include appropriate tables of strata and zones of fossils. In particular, the diagrammatic sections which illustrate the various excursions greatly assist in the identification of strata.

The young and active of all ages will find in "The Dorset Coast" a happy combination of serious study and stimulus to exploration, which will enrich and repay a visit to one of the finest stretches of English coastal scenery.

Flore des Spermatophytes du Parc National Albert

3: Monocotylées. Par Dr. Walter Robyns, avec la collaboration de Roland Tournay. Pp. 571 (76 plates). (Bruxelles: Institut des Parcs Nationaux do Congo Belge, 1955.) n.p.

THE third volume of the Flora of the Albert National Park in the Belgian Congo maintains the high tradition set up by the two former volumes. The production of the volume is of a very high standard, the printing being excellent, and the botanical treatment is that to be expected from a botanist of Prof. W. Robyns's international reputation.

The present volume is concerned with the monocotyledonous plants of this vast area, lavishly illustrated by excellent line-drawings and half-tone plates. Without doubt this work will find a place in all institutions concerned with the vegetation of Africa, and it can be recommended to the numerous visitors to one of the show-places in the Belgian Congo.

N. L. BOR

Reports on the Progress of Applied Chemistry

Vol. 39: 1954. Pp. 1125. (London: Society of Chemical Industry, 1955.) 60*s.* (40*s.* to members).

PRINTING difficulties have not, fortunately, greatly delayed the appearance of this well-known yearly expected survey of applied chemistry. The publication by the Society of Chemical Industry of this comprehensive and authoritative annual review is the result of a remarkable effort of collaboration by the hundred or so contributors, the indexers and the editor.

In these days, applied chemistry has wide ramifications among related sciences, and one finds in these pages sections on antibiotics, on the control of agricultural and horticultural pests, on general microbiological processes and on toxicological hazards; although, as one would expect, attention is mainly given to such topics as acids, alkalis and salts, metals, fuels, tar, petroleum, organic chemicals, intermediates and drugs, to mention only a few. Indeed, all aspects of applied chemistry are covered in sections of appropriate length, and the usefulness of the compilation is enhanced by the provision of very extensive bibliographies with each section (that on petroleum, for example, has five hundred references to original literature) and a detailed subject index for the work as a whole.

Every chemical library will need this volume; every active chemist, no matter what his speciality, will find it a source without rival of digested, up-to-date knowledge.

Ciba Foundation Symposium on Porphyrin Biosynthesis and Metabolism

Edited by G. E. W. Wolstenholme and Elaine C. P. Millar. Pp. xii+308. (London: J. and A. Churchill, Ltd., 1955.) 30*s.* net

THE Ciba Foundation symposium on porphyrin biosynthesis and metabolism in February 1955 covered a wide field of biological interest. About one-third of the nineteen papers dealt with the biosynthetic pathway in hæm synthesis and the role of δ-aminolævulic acid, porphobilinogen and porphyrins in hæm formation. A paper on the succinate–glycine cycle stressed the view that the formation of δ-aminolævulic acid represents a major aspect of glycine metabolism.

To the bacteriologist and plant biochemist the papers on the formation of porphyrins by photosynthetic bacteria and of porphyrins and chlorophyll in the alga *Chlorella* will be of interest. There are two papers on aspects of hæmoglobin metabolism which should prove of particular note to the hæmatologist. The reports of the properties of δ-aminolævulic acid dehydrase, of the metabolism of δ-aminolævulic acid and porphobilinogen and of the mechanisms of experimentally produced porphyria are of importance to the eventual understanding of the human diseases of porphyrin metabolism. There are also papers on the biosynthesis of hæmin chromoproteins in animal tissues, with special reference to cytochrome *c*, and also one on the synthesis of uroporphyrin II and IV.

The full reports of the lively discussions after each paper add much to the value of this book. They reveal the areas of acceptance and controversy and clearly suggest fruitful lines for further work in this rapidly developing field.

A. GOLDBERG

POWER PRODUCTION AND CONSUMPTION

THE Fifth World Power Conference took place in Vienna during June last, the only other meeting since the Second World War having been held in London in 1950. There were thus the results of six years of progress to consider. Some 275 papers from thirty-five nations, including the U.S.S.R., were presented, covering a very wide field divided for convenience into five divisions, each division being sub-divided into several sections. The classification was as follows: Division I: The Present Status and Development of Power Production and Utilization in National Economy (58 papers); Division II: Preparation and Conversion of Fuels (55 papers); Division III: Utilization of Primary Sources of Energy (137 papers); Division IV: Purification of Waste Water and Exhaust Gas (8 papers); Division V: International Co-operation in the Production and Use of Energy (11 papers). It is only possible in this review to comment briefly on the trends noticeable in the general reports covering the contents of the several papers presented in each section.

The picture presented of the relation between power consumed and the available resources of fossil fuels is on one hand encouraging, in that there has been an increase in the power consumed in the whole world, and on the other hand perturbing, in that the proved reserves of all fossil fuels show little signs of supplying economically the required energy for any considerable period of time. Estimates of fuel reserves differ, and some countries are much better off than others; but it appears as a virtual certainty that the exploitation of nuclear resources and the vast but inconvenient, and at present uneconomic, potentials of water, wind and sun will be rapidly forced upon industrial nations.

Coal production is a major problem in most countries, except in the United States, where the known reserves are 10,000 tons per capita as against, for example, 0·43 in Austria. In India and in Britain coal production has actually declined. Perhaps the most important general observation of the world coal situation which may be made is that it is the difficulty of obtaining the right type of coal for particular applications which is of greater moment than the actual quantity produced. For example, the rapid increase in steel production together with the decrease in availability of suitable coking coals are causing considerable research to adapt less suitable coal to coking methods. In 1955 pulverized coal consumption was 19 million tons in Britain as opposed to 8 million tons in 1950. In twenty years in the Federal German Republic, refuse in hard coal mines rose to 24 per cent—double its previous figure. Methods of handling, washing, cleaning and processing coal are therefore being improved as its value appreciates, and quality falls.

The use of petroleum is increasing at a greater rate than that of coal and now accounts for about one-third of the total world energy demand. An interesting point is that while the United States is still incomparably the world's largest consumer of petroleum products (53 per cent), the proved reserves of Saudi Arabia and Kuwait are together more than double those of North America.

The trend in the utilization of raw oil varies slightly in different countries. In Great Britain since 1950 there has been a decline in the proportion of oil used for petrol, a small increase in that used for diesel fuel, and a larger increase in the proportion of distillates and residuals for furnace oil; a similar trend occurred in the German Federal Republic. This was in contrast with the United States, where the percentage demand for residuals rose only slowly, while the demand for petroleum fuels and medium distillates increased briskly due to use for jet aircraft, diesel locomotives and motor fuels. There appears to be a relative increase in the use of diesel engines in all the major industrial countries, excluding Japan, where curiously there is a pronounced decrease.

The most striking development of the petroleum industry is the advance in the refining technique and the improved method of production of various grades of end-products. In particular, catalytic cracking and re-forming plants have largely replaced thermal plants. Demand for and production of high-octane motor petrols have both increased, the premium grade octane number now being greater than 90, compared with 80 in 1940. The diesel fuel situation shows less improvement, as diesel running costs are kept low by engines prepared to digest a wide fuel cut. However, desulphurization processes are likely to be improved.

The gas industry is often regarded by the general public as an obsolescent concern. In fact, this is far from the truth. The extension in the use of natural gas in those countries blessed with this resource is quite remarkable. In the United States, some 25 per cent of the total power supplied comes from combustion of natural gas. In Britain, experiments have been carried out to obtain gas from coal of high ash content directly out of the seam. It is perhaps significant that it has been found necessary to devote a complete section to the discussion of long-distance transmission of gas. Natural gas reserves are being exploited, particularly in the United States, Italy and France, and a long-distance line of some 1,100 miles has been completed in the Argentine. With such developments it may soon be feasible to transport natural gas from the Middle East oil-fields to the extreme west of Europe. It is already possible to transport cooled liquefied ethylene in railway trucks, and some authorities expect that liquid methane will be transported by tanker from the Middle East. An interesting problem, to quote the general report, will be "to find some use for this large quantity of cold which will be liberated when vaporizing the liquid methane at the place of delivery".

In countries with no natural gas supplies, the use of gas is also increasing. This is due to gas production as a by-product from the coke and oil-refining industries, and the realization that the gases from blast furnaces may be integrated into a gas grid system. Several countries are considering use for the methane obtained from mine ventilation; possibly this may be burnt in a gas turbine if the mixture is weak, or, as in the Saar, supplied to cracking plants, before feeding to the grid. The economic use of sewage gas is discussed only in a paper from Britain, where sludge gas is used to drive dual-fuel engines or gas turbines.

The fact that the percentage produced by water of the total electrical power consumed has decreased in both Europe and America, should not conceal the great advances made in the quantity of power produced hydraulically, or the improvements in that science. Most countries have made extensive investigation of their hydraulic resources. Improvements in long-distance transmission of electricity have encouraged developments of hydraulic projects distant from industrial centres. The general tendency is for schemes to be planned as multi-purpose works where flood control, irrigation or navigation benefit, in addition to the production of electric power. Data of water power available, compared with that utilized, show that while Europe, particularly in Italy, Sweden and Switzerland, is near the possible economic limit of development, less water power is produced in Africa than in any other continent, though its potential is by far the largest. The potential of South America is considered to be less than that of Europe. Experimental techniques, such as the use of models and photo-elastic analysis of dam stresses, are now more in evidence in the design stage, while during construction improvements have been rather in details and in constructional technique than in fundamentals. One feature is the popularity of underground power houses. The huge Kemano project in Canada envisages a chamber 1,146 ft. × 82 ft. × 131 ft. to house 2·4 million h.p. The capacity of the units in the larger projects has been raised; for example, Kaplan turbines of 111,000 h.p. at McNary, U.S.A., Francis turbines of 165,000 h.p. at Grand Coulee, U.S.A., and Pelton wheels of 150,000 h.p. at Kemano and Cimego, Italy. The efficiencies of machines have also risen, average figures quoted being 93 per cent for Kaplan turbines, 92 per cent for Francis turbines, 91 per cent for Pelton wheels. The maximum single-generator capacity is 160 MW. (Stornorrfors, Norway), while plants with an overall output of 100 MW. are now considered of medium size. Kaplan turbines handle heads up to 776 ft., Francis turbines up to 1,476 ft. and Pelton wheels up to 5,740 ft.

Apart from the orthodox hydraulic schemes, some progress has been made with the long discussed possibility of harnessing tides. Electricité de France intends to erect a tidal-power plant at the mouth of the Rance. Turbine and generator will be reversible, so that power may be produced both on flood and ebb tides. There are thirty-eight units, each consisting of a Kaplan turbine and alternator, the total output being 9,000 kW. Further schemes for the Chausey and Minquiers Islands are projected.

The sections on atomic energy are not quite so large as might have been expected in view of the intense interest aroused by this subject. This is probably due to the short interval since the end of the International Congress on the Peaceful Uses of Atomic Energy held in Geneva last year. In view of the evident shortage of world coal and oil supplies, the importance of the discovery of large resources of fissile material cannot be over-emphasized. It can scarcely be expected that these resources have been determined to even a fraction of the degree of accuracy to which those of petroleum and coal are known. Nevertheless, conservative estimates suggest that the energy available, even with relatively low station efficiencies of 18 per cent, is at least an order greater than that from fossil fuel resources.

The state of reactor design would appear most satisfactory: precisely because no one type has yet been shown to have decisive advantages. Thus many variations are under construction or in use in a single country. Broadly, reactors are of two types, the heterogeneous reactor, in which rods of the fuel element are distributed throughout the moderator and a coolant is passed through the reactor core, and the homogeneous reactor where the fuel and moderator are intimately mixed, for example, as a solution, the solution itself being circulated through a heat exchanger. Within this broad classification many important differences of design may arise. It is, for example, by no means clear what are the most suitable combinations of moderator and coolant, or what is the better choice between thermal and fast reactors. In Britain, the Calder Hall Station uses natural uranium with a graphite moderator and compressed carbon dioxide as a coolant. This type of reactor suggests a relatively low cost per kW. output and a high safety factor, an over-riding consideration in a densely populated country. Graphite reactors with water and liquid sodium cooling are in use in the U.S.S.R. and the United States. Water may be used as both moderator and as coolant and, if allowed to boil, may be fed directly to a turbine. In the United States, a boiling-water 2-MW. plant is in operation, a 5-MW. plant under construction and a 180-MW. plant planned. Fast reactors are also undergoing development; but no report on their progress was submitted to the Vienna Conference.

After further development, homogeneous reactors are likely to be as popular as the heterogeneous reactors; they have certain technical advantages, but to cope with the high pressures at which they must operate to ensure good thermodynamic efficiency and to provide them with heavy water solvent or enriched uranium, the capital cost is high. Both the United States and the Netherlands are carrying out such development.

The main problem in the application of the reactor to power production is the low temperatures which can be withstood by the constructional materials of the reactors while still preserving low neutron absorption and hence fuel economy. The problem is largely a metallurgical one, and progress is being made. The attention paid to building nuclear power stations varies directly with the degree of a nation's industrialization, and with the scarcity of its available reserves of fossil fuels. It is thus not surprising to find Britain in the forefront of commercial development with a proposed programme of twelve plants of a maximum possible output of 2,000 MW. by 1957, and that by 1975 it is planned that equal amounts of electricity shall be yielded by coal and atomic plants. International opinion differs as to the desirability of producing atomic power. The correct solution must depend upon the local economics. The situation in Britain, where coal production is on the decline, must involve an entirely different solution from that in the United States, where in some cases it is only economic to exploit 55 per cent of a coal seam, so plentiful are reserves.

Whatever the form of thermal energy producer most economic in the future, the energy produced will be largely utilized as electrical energy. In Europe (not including the U.S.S.R.) there seems to be an annual increment of 8 per cent in the electricity consumed, which suggests that the electrical output may about double itself in a decade. The demand for electrical energy, 5 per cent of the total energy demand in Europe, is rising at almost twice the rate of the total energy demand. Excluding the U.S.S.R., China and Eastern Europe, the 1954 index was 137 units compared with 100 in 1948.

There is, therefore, more than ever a widespread interest in thermal power stations, of which the turbines and generators at least are likely to be the instruments of power conversion from nuclear reactors. With the decrease in availability of coals, it is becoming essential that power stations shall generate at the maximum efficiency and thus steam-plant design is becoming more complicated. Multiple reheat and bleed-steam preheating systems using up to nine stages are being applied, more perhaps in the United States than in Europe, to approach more closely the Carnot cycle.

A whole section was devoted to the construction and operation of steam boilers. In the search for higher efficiencies, steam generating temperatures have risen by 18° F. per annum, the maximum value now being about 1,200° F., a temperature at which austenitic steels must be used. Below this a gap in the range exists, the maximum temperature feasible for ferritic steels being about 1,000° F. Operational pressures have risen to very high figures, especially when reheat is introduced; two commercial examples are 1,150 and 2,850 lb. per sq. in., while experimental plant uses up to 5,000 lb. per sq. in. Average boiler capacities have risen to between 450,000 and 900,000 lb. per hr., with some boilers generating 2,400,000 lb. per hr. Boiler efficiencies of 90 per cent are reported and availability is nearly 100 per cent. Boiler systems are largely orthodox, of the natural circulation drum type, but forced circulation monotube boilers are used to an increasing extent, particularly on the Continent of Europe. Design of boilers is also being influenced by the necessity for burning inferior coals with their more acute flue cleaning and ash disposal problems. One new method of cleaning the convection heating surfaces on load is to pour small steel balls over the tubes, and collect them in the ash hopper, where they are removed from the ash and cleaned.

Steam boilers appear to be in their heyday, possibly at about the stage of development of the reciprocating engine in the year 1900. No doubt bigger and better boilers are yet to come; but, to quote the general report, "it seems that developments in the field of atomic energy will outdate endeavours towards a further improvement in existing methods of power generation". Steam generation by nuclear reactor heat is the problem of the immediate future. The temperatures available are unfortunately low, 500° F. with water-cooled, possibly 750° F. with sodium-cooled fast breeder reactors. It is suggested that compound plants where superheating is accomplished by oil firing may be evolved.

Many other aspects of power generation are treated by one or more papers. Developments in the use of solar energy—never of great concern in the temperate zone—have progressed to some extent; but direct use of the sun's heat is still inconvenient and usually uneconomic. Even in India the preference of an oriental population for preparing their meals in the evening has reduced the sale of solar cookers. Heat pumps and fuel cells, the latter of great academic interest, are discussed in British papers, while complete sections are devoted to statistical compilation of data, purification of industrial effluents, and the technical and economic aspects of international co-operation.

The tremendous field covered at the Conference must be apparent from the number of papers presented by thirty-five countries. It is inevitable that somewhere the field must be bounded and that all the field may not be covered in the detail some would wish. For example, the application of power to transport, the developments of gas turbines and diesel and free-piston engines are only briefly considered. It is also disappointing that more attention was not given to the reminder of the president, Sir Harold Hartley, who said in his address: "Food is the most urgent need of the world to-day and I would ask you if we are devoting enough thought to the place of power in agriculture as compared with the emphasis we place on industry. . . .".

Generally, the tone of the Conference was optimistic, in spite of the shadow cast by falling fuel resources: the tone seems to be one of certainty that more and more power will be needed, combined with an equal certainty that a wider search for power reserves, coupled with a more effective use of known resources, and development of nuclear reactors, will provide that power. Finally, a word in praise must be said for the general reports summing up the proceedings of each section. These are admirably translated into French, German and English, and are remarkable for their concise and balanced interpretation of the mass of technical data presented. They are worthy of an international conference, which presents a remarkably clear picture of present-day practice and of the directions in which scientific research in power production is leading.

F. D. Robinson

ANIMAL REPRODUCTION

THIRD INTERNATIONAL CONGRESS IN CAMBRIDGE

The Third International Congress on Animal Reproduction, attended by more than five hundred representatives of no fewer than fifty different countries, was held in Cambridge during June 25–30. The proceedings were conducted in three sections, devoted to physiology, pathology and artificial insemination, respectively. About one hundred and fifty papers were presented, many of which were concerned with the practical aspects of animal-breeding, clinical problems, and technical advances in the methods of semen storage and artificial insemination. A noteworthy feature of the Congress, however, was the relatively high proportion of papers of more general scientific interest, dealing with the physiology of mammalian gametes and the early stages of embryonic development. The growing impact of two fundamental sciences in particular, namely, biophysics and biochemistry, on research in the field of animal reproduction, was specially evident from the nature of the Congress exhibits and demonstrations, many of which were provided by the scientific staffs of the Agricultural Research Council Unit of Reproductive Physiology and Biochemistry and other departments in the University of Cambridge.

A large number of original contributions dealt with semen physiology, bearing witness to the impressive advances in this field, which continues to expand in several directions. One of these concerns sperm morphology and motility; here the advent and perfection of powerful aids to research, such as electron and phase-contrast microscopy, photography in ultra-violet light, the application of fluorescent dyes, and a steady improvement in staining methods which permit the differentiation between live and dead spermatozoa have all helped to open up new possibilities towards the elucidation of the finer structure of spermatozoa. As a result of these studies, much has been learned in recent years about the fibrillar structure of the sperm-tail in relation to sperm motility, and the properties of the acrosome in relation to the 'cold shock' and other phenomena associated with senescence changes in spermatozoa. A second line along which research on spermatozoa has been rapidly developing relates to the survival of sperm cells at very low temperatures. Much of this research was inspired by the observation, made a few years ago, that better sperm survival can be achieved when semen is frozen in the presence of glycerol. The same approach has now been extended to the tissues of the gonads themselves. In addition to several communications on the practical application of glycerol in low-temperature storage of bull semen, two papers dealt with the broader physiological aspects of cellular damage resulting from freezing and with the principles underlying the ability of gametes and grafted gonadal tissues to survive in the frozen state. Yet another line along which progress in sperm physiology is being vigorously pursued is the biochemistry of semen. This was quite obvious from the large number of contributions on such problems as the incorporation of radioactive elements into the male gamete, the relation of respiration and fructolysis to sperm motility, the function of seminal hyaluronidase, and the role of mineral constituents in semen, particularly that of potassium ions which, judging from no less than three independent studies, play an important, hitherto largely disregarded, function in eliciting sperm movements.

One of the outstanding problems in reproductive physiology concerns the mechanism which enables the spermatozoa to traverse the female reproductive tract before reaching the site of fertilization, and in this connexion much work has been carried out in recent years on the metabolic processes associated with sperm movements. An important aspect of that research is the elaboration of methods for measuring sperm motility. Several valuable methods have been evolved in recent years; but there is still room for new objective and quantitative procedures. At least one more such technique was reported upon at the Congress, involving the use of a photo-electric cell for registering the movements of single spermatozoa. Strong evidence, however, is steadily accumulating which indicates that apart from motility inherent in the sperm cells, there are other factors which facilitate sperm transport in the female reproductive tract. There is much to show that spermatozoa do not depend entirely upon their own motility but are, in addition, propelled, as it were, by the concomitant contractions of the uterus. These uterine movements, judging from papers presented at the Congress, are dependent on the co-ordinated action of the neurohypophysis and hypothalamus. Another phenomenon frequently discussed during the Congress was the so-called sperm-capacitation, which appears to depend on certain peculiar, but as yet poorly understood, changes taking place in spermatozoa before they reach the site of fertilization, and enhancing the fertilizing capacity of the sperm cells.

Whereas the advanced stages of gestation have long been the target of choice for physiological research, data on the mammalian egg and the pre-implantation or near-implantation phases of mammalian pregnancy continued to be rather scarce until recently. However, now that methods for the transfer of mammalian eggs from a donor to a recipient have been greatly improved upon, it is possible to apply these techniques to the study of fertility and the development of normal and abnormal ova in the female reproductive tract. Several speakers dealt at some length with the manifold aspects of the technique of egg transplantation, chiefly in the sheep and the rabbit. Research in this field seems to concentrate largely on perfecting the existing means for preservation of mammalian eggs *in vitro*, and the elaboration of new techniques which would dispense with the need for laparotomy during the transfer of eggs. Results of fruitful research on the physiology of the mammalian egg were presented to the Congress in several communications, some of which dealt with the biochemical relationship between the early embryo and the uterine environment, whereas others described measurements of oxygen uptake by rabbit ova at different stages of development. Varied aspects of reproductive physiology covered by speakers included also attempts at determining the content of oxygen in the Fallopian tubes of the rabbit, and new findings on certain rheological and spectrophotometric properties of secretions collected from the female reproductive tract.

A large group of papers presented at the Congress dealt with the nutritional and hormonal aspects of animal reproduction. Several authors pointed out that the two principal functions of the male and female gonad, namely, the gametogenic and endocrine activity, are by no means equally sensitive to a given nutritional deficiency, and that in many instances, particularly where certain vitamins, proteins and minerals are concerned, the hormonal function of the gonads is affected earlier than gametogenesis. Much useful information on the role of nutrition and hormones in reproduction has been forthcoming from studies of monozygous twins. Two new chemical methods of tackling the problem of malnutrition in reproduction were communicated: one based on the analysis of semen collected from twin bulls, for the assessment of nutritional factors which control the secretory activity of male accessory organs; the other involving the analysis of the mineral content of hair samples taken from the poll region of cattle to serve as an indicator test for an early diagnosis of certain mineral deficiencies.

Among clinical problems fully discussed at the Congress, two received particular attention, judging from numerous communications, namely, the deleterious effect of certain infections (brucellosis, *Vibrio foetus*, *Trichomonas foetus*) on animal reproduction, and the occurrence of genital malformations as a cause of infertility.

T. MANN

THE PHYSICS OF SEMICONDUCTOR SURFACES

SURFACE physics has not usually been thought of as a particularly exact science. The experimental difficulties in obtaining meaningful measurements under well-controlled chemical conditions, and the theoretical difficulties of proceeding beyond a mere thermodynamical description to an atomistic, quantum-mechanical one, have alike tended to keep surface physics on the by-ways of science. It is, nevertheless, a field which is of growing importance, in physical science, in biological science and in technology. A measure of the progress recently gained may be gathered from the scope of a conference on the "Physics of Semiconductor Surfaces", held in Philadelphia last June. The conference, which was sponsored by the Office of Naval Research, Lincoln Laboratories, and the University of Pennsylvania, included representatives from Canada, France, Germany, Great Britain and the Netherlands, as well as the United States. Although much of the conference was devoted to the surfaces of silicon and germanium, there were contributions from chemists in the fields of oxidation and catalysis. The papers presented at this conference are to be published in book form in the near future by the University of Pennsylvania Press. In the meantime, a brief review of the conference, and a few comments on one or two of the papers—picked almost at random—will be given in this short account.

Two things have helped to promote progress in surface physics during the past ten years. One is the development of techniques for carrying out experiments in ultra-high vacuum. An atomically clean surface, kept in a vacuum of 10^{-10} mm. of mercury, should have a monolayer adsorption time of several hours—long enough to perform detailed measurements on it. The other stimulus—and the one more immediately responsible for the promotion of the Philadelphia conference—has come from the invention of the transistor and, with it, the availability of germanium and silicon in a state of very high purity. This means that one can now carry out experiments on a surface system in which it is possible to change the electrochemical potentials of holes and electrons at will by known amounts. It also means that, because the surface space-charge region extends relatively far into the semiconductor, the several contributions to the overall variation of electrostatic potential across the interface may each be determined quantitatively. The ability to distinguish the different parts of the surface dipole has hitherto been lacking in the analysis of solid–gas surface systems, although there is a rough analogue in electrochemistry, in the measurement of zeta potentials. The material presented at the conference affords a good illustration of these developments.

Many of the papers dealt with surfaces of germanium and silicon, as prepared by etching and maintaining in some gaseous environment. Here the physicist can make detailed measurements on the positions of electronic energy-levels associated with the surface, and of transition probabilities between these levels and the interior of the semiconductor. The physicist distinguishes between 'fast' and 'slow' states. The 'fast' states, characterized by relaxation times of less than a microsecond, must be associated with the actual germanium or silicon surface; the 'slow' states have relaxation times of the order of a second or longer and, in the present state of knowledge, are imagined to be associated with the oxide layer. Several papers gave quantitative information on the distribution of the 'fast' states in the forbidden energy gap, and on the capture cross-sections for these states. The most valuable experimental tools here are the effects of applying a high electric field in a direction normal to the surface, and of illuminating it. Other papers dealt with the 'slow' states and the probable connexion between these states and ($1/f$) noise.

All these experiments suffer from the drawback that the chemical constitution of the surface region is almost completely unknown, and largely uncontrollable. Many workers have therefore tackled the problem of carrying out similar measurements on an atomically clean surface, and then allowing various impurities to be deposited upon it, so that the effect of each one may be studied. P. Handler reviewed the experimental results obtained by the Farnsworth technique of ion bombardment and annealing in ultra-high vacuum. The most outstanding conclusion here is the unexpectedly high surface conductivity found after the surface has been prepared in this way. It was generally agreed that the Farnsworth surface is p-type, becoming less so as the surface is exposed to reasonable amounts of oxygen. There is quite good agreement between the findings of the various research teams working in this field. These facts, if they do indeed refer to the properties of an atomically clean surface, are of the highest importance, because this is the only case so far for which it has been possible to give anything approaching a respectable theoretical discussion. The theory of surface states was discussed by C. Herring, who directed attention to the Tamm and Shockley states associated with a perfect semiconductor–vacuum interface, and to the various kinds of level arising from surface impurities and imperfections.

Turning to matters of chemical interest, there was an excellent series of papers on the electronic aspects of catalysis. K. Hauffe discussed his work on the effects of the surface space-charge region on catalysis at semiconductor surfaces. G. M. Schwab presented a selection of experimental results, some of them obtained with germanium—which, he said, is not a very good catalyst, but illustrates the consequences of the theory quite nicely. The final session of the conference was devoted to surface oxidation, including a discussion of nucleation effects, by N. Cabrera, and several papers on the surface oxidation of germanium under various conditions.

The general level of the papers and discussions was exceptionally high, and most people seemed to feel that both the formal and the informal activities at the conference were profitable and stimulating. Surface physics is in a very exciting state of growth at the moment, and, if the purist views the current heavy emphasis on silicon and germanium with a somewhat jaundiced eye, he may take comfort in the expectation that the techniques and understanding developed with these materials will be of direct usefulness in the study of other surface systems.

C. G. B. GARRETT

OBITUARIES

Prof. E. J. Friedmann

PROF. ERNST JOSEF FRIEDMANN died in Cambridge on July 19 at the age of seventy-eight; he was working in his laboratory on the previous day. Born in Berlin and educated at the College Royal Français, he studied at the Universities of Freiburg im Breisgau, Berlin, Würzburg, Leipzig and Strasbourg, and took the degrees of Ph.D. in 1902 and M.D. in 1905 at Strasbourg. During 1905–7 he was a member of the staff of the Institute of Physiological Chemistry in the University of Strasbourg. There he worked under Prof. Franz Hofmeister, to whose influence he attributed much of the success of his career and in whose laboratory he acquired his characteristic meticulous care in all matters of practical technique in the highest tradition of the German school. In 1907 he went to Berlin as head of the Department of Physiological Chemistry at the First Medical Clinic of the Charité, with the title of professor in the Medical Faculty of the University. During the First World War, he directed (1915–18) the Bacteriological Laboratory of the German Army in Brussels. In 1930, he went to Moscow as professor of biochemistry but left after six weeks. He then went to Basle and worked at the Institute of Physiological Chemistry of the University.

In 1932 Friedmann came to Britain to work in the Department of Biochemistry in Cambridge with Sir Frederick Gowland Hopkins. Shortly afterwards his wife was taken seriously ill and died after a long illness, during which everyone was most impressed by his devotion to her. He remained in Cambridge not only because the political conditions in Germany made it impossible for him to return, but also because he had found a congenial atmosphere in Cambridge where Sir Frederick Gowland Hopkins had befriended him and encouraged him to continue to work in his Department. In 1941 he joined a research team engaged in work of national importance for the Agricultural Research Council. In 1946 he came to the Department of Radiotherapeutics of the University of Cambridge, where he worked until his death.

Friedmann's first paper was published in 1900 and he continued active research from then until the end of his life. Many of his papers are now classical, including two papers, "Über die Konstitution des Cystins" (*Bei. chem. Physiologie u. Pathologie*, 3, 1–46; 1902), and "Die Konstitution des Adrenalins", (*Bei. chem. Physiologie u. Pathologie*, 8, 95–120; 1906). He then wrote a series of twenty-five papers under the general title "Zur Kenntnis des Abbaues der Karbonsaure im Tierkörper" published between 1908 and 1914 in the *Beiträge zur chemischen Physiologie u. Pathologie*, which during this time became the *Biochemische Zeitschrift*. Among his other earlier papers, Dr. Friedmann regarded as the most important those dealing with the constitution of mercapturic acids, the synthesis of *iso*leucine, the synthesis of surinamine and the formation of ketone bodies.

In Cambridge he started to publish papers on the chemistry of œstrogenic substances. The first of these was a letter in *Nature* (135, 622; 1935). At the same time his interest in sulphydryl compounds first appeared. His book entitled "Sterols and Related Compounds" arose from three lectures which he had given at the Institute of Biochemistry in Cambridge and was published in 1937. These lectures and the book had a great influence.

It was characteristic that Friedmann always kept in touch with the most recent work and modern approach and methods, as exemplified by his studies of radioactive organic bromo-compounds published in collaboration with A. K. Solomon and N. T. Werthessen in 1939. At that comparatively early stage he had already perfected methods for labelling organic compounds with radioactive halogens and advocated their use in biological research. Since 1946 he has published an interesting series of papers on anti-mitotic agents, particularly of the quinone series, which as a rule were tested on tissue culture. These papers were mainly written in collaboration with Mrs. I. Simon Reuss and Dr. D. H. Marrian.

Most of us knew him only after he came to Cambridge; but we soon saw in him not only a great scientist but also a man of wide cultural background. Brought up in Berlin as the son of a wealthy banker during an era which was famous for its gracious living, he had a great appreciation of beautiful things. His main interests, outside his work, were books, antique furniture and Chinese art, and concerning these he had a tremendous fund of knowledge. He also liked to read detective stories when he felt too tired to work at night. Life had dealt him disappointments, but he never complained and never became embittered. His old-world courtesy was one of his most charming assets. He was always especially kind to younger workers, and never hesitated to spend a great deal of time discussing their work and helping them with their problems from his vast experience and enormous knowledge. He died in harness and, to judge by the vast amount of unpublished experimental data which he left, as active as ever. He leaves a host of friends who will cherish his memory.

J. S. MITCHELL

Mr. T. D. Bourdillon

THOMAS DUNCAN BOURDILLON met his death on July 29 while climbing in the Swiss Alps. He had established a world-wide reputation both for his skill as a mountaineer and his more specialized achievements in the art of rock climbing. Through the writings of others he became well known to the general public as a member of several Himalayan expeditions, of which the last was the successful one led by Sir John Hunt in 1953. His contribution to this success lay not only in his inclusion as one of the strongest members of the climbing party, but also in his preparatory researches and development work on the oxygen equipment used, which has been described in the *Proceedings of the Royal Society*, B, 143, and in the *Alpine Journal*, 59.

From Gresham's School, Holt, Bourdillon went up to Balliol College, Oxford, in 1942, and was in residence there until June 1944, at which time he joined the Army. From then until April 1948 he served in Greece and Egypt, and returned to Oxford in October 1948, where he read the honours course in physics and received his degree in June 1950. On coming down from Oxford he joined the Ministry of Supply and was appointed as an experimental officer to the Royal Aircraft Establishment, Westcott, where he worked on problems connected with rocket propulsion.

During 1951, 1952 and 1953, he was given leave of absence, to participate in the two preparatory Himalayan Expeditions which culminated in the successful one in 1953. Since that time he has been engaged fully on his rocket work and has made a notable contribution to our understanding of the phenomena of combustion of solid propellants. Although primarily a skilled experimental physicist, he possessed considerable practical engineering ability which stood him in good stead when acting as project officer responsible for the overall development of particular rocket motors. His work at Westcott portrays those innate characteristics which were so ably demonstrated in his mountaineering achievements, namely, scrupulous attention to detail, careful deduction and intellectual honesty.

No doubt Bourdillon will be remembered as a mountaineer first and foremost; but among his colleagues at Westcott there will remain the respect for a man of great personal integrity and a genuine modesty.

He leaves a widow, Jennifer, who shared fully his interests in mountaineering, and two young children.

J. E. P. Dunning

Mr. and Mrs. John Nicol

Mr. John Nicol, officer-in-charge of the Ibadan Sub-station of the West African Cocoa Research Institute, died from injuries received in the air disaster at Kano, Northern Nigeria, on June 24; his wife, Mrs. Bessie Nicol, was killed instantly. They were travelling on leave and to a re-union with their only child, Sheila, who is at school in Scotland.

The details of Nicol's complete career at present available to his colleagues in West Africa are meagre; but records reveal that he was born in 1911 and he graduated at the University of Aberdeen with a B.Sc. degree in forestry. After working for some years with the Department of Scientific and Industrial Research in the United Kingdom on the pests of stored products, he came out to the West African Cocoa Research Institute, Gold Coast, a few weeks after its inception in 1944. He was afterwards promoted to senior entomologist and was posted as officer-in-charge of the sub-station in Nigeria of the Institute in December 1954.

John Nicol's early work in West Africa was concerned with measures for the control of cacao capsids. Later, he became associated with trials concerned with the possibilities for controlling the spread of cacao swollen shoot virus by attack on the mealybug vectors with systemic insecticides.

As a founder-member of the staff, John Nicol had much to do with fostering the social life at Tafo, and with these activities, later extended to Ibadan, Bessie Nicol must be closely identified. The construction of the club, the tennis courts and the golf course (the latter being coupled with a malaria-control project) were all, in considerable measure, due to his enthusiasm.

'Nick', as he was widely known, was a talented photographer, his ability being recognized by election to the associateship of the Royal Photographic Society. Many of his photographs of cacao, its pests and its diseases have been published in technical papers by himself or his colleagues.

As officer-in-charge of the Ibadan Sub-station, John Nicol was faced with many difficulties. His gift for making friends and marshalling facts into convincing arguments enabled him to make considerable progress in establishing and equipping a new laboratory and staff accommodation. His untimely death is a severe blow to the progress of cacao research in Nigeria.

James Lamb

NEWS and VIEWS

Physical Chemistry in the University of Sydney: Prof. A. E. Alexander

Prof. A. E. Alexander has been appointed professor of physical chemistry in the University of Sydney. Prof. Alexander was educated in the Universities of Reading and Cambridge. He began research in Cambridge in association with Sir Eric Rideal and quickly became well known for his contributions to surface and colloid chemistry. During 1939 he worked with Prof. T. Teorell, of Upsala, with a Rockefeller travelling fellowship. On his return to Cambridge he became a Fellow of King's College and, in 1944, assistant director of research in the School of Colloid Science. Prof. Alexander went to Sydney in 1949 as the foundation professor and head of the School of Applied Chemistry in the New South Wales University of Technology, in which he is now dean of the Faculty of Science. He has taken a full part in the scientific life of Australia, having been president of the New South Wales Branch of the Royal Australian Chemical Institute, and of the Sydney University Chemical Society. He is a trustee of the Australian and New Zealand Association for the Advancement of Science, which selected him as the Liversidge Lecturer for 1954, and one of the two representatives in Australia of the Chemical Society of London. He has established excellent relations with the Commonwealth Scientific and Industrial Research Organization and Australian chemical industry. Prof. Alexander's many research papers and books on surface and colloidal science have brought him well-deserved international recognition. His present range of scientific interests—the pure physical chemistry of problems underlying various biological actions—will add welcome strength to the University of Sydney.

Electronics in Armament Research and Development: Mr. E. W. Chivers

Mr. E. W. Chivers, who has been appointed principal superintendent of the Electronics Division of the Armament Research and Development Establishment, graduated in physics (special) with honours in 1927 at Queen Mary College, London. After a short period of postgraduate research, he entered Government service in 1928 and went to the Research Department, Woolwich, where he was engaged on acoustical research in connexion with sound ranging. In 1931 he was transferred to the Searchlight Department at the Air Defence Experimental Establishment, Biggin Hill. His work there was concerned with physical problems associated with searchlights and their use, later extending to problems of searchlight design and automatic control. In 1940 he was transferred with the remainder of the Biggin Hill Establishment to Christchurch to join with the Army radar group which had been transferred from Bawdsey. There he became leader of the team responsible for the application of radar to the control of searchlights, the introduction of which into the Services made such a great improvement in searchlight operation. He continued in radar work when the Establishment (by then the Radar Research and Development Establishment) was transferred to Malvern, and was concerned with a number of Army radar projects throughout the War. In 1953, when the Radar Research and Development Establishment and the Telecommunication Research Establishment were combined as the Radar Research Establishment, he was promoted to deputy chief scientific officer and became head of the division responsible for ground radar for both the Army and the Royal Air Force. In 1954 he was appointed director of atomic weapons (development and production) at the Ministry of Supply Headquarters.

Reactor Conference at Harwell

The United Kingdom Atomic Energy Authority announces that a conference at Harwell will be held on November 30, at which its programme of research on advanced types of nuclear power reactor systems will be explained to representatives of British industry, and at which the salient features of the particular systems which have been chosen for investigation will be described. Accommodation will be available for about two hundred representatives from industry. Requests for further details and for reservations should be made to the Director (Industrial Collaboration Office), Atomic Energy Research Establishment, Harwell, Nr. Didcot, Berks, not later than August 31. The Authority intends that following this conference British firms wishing to do so may be kept informed of the general progress of work on these reactor systems. The information will be supplied at an annual conference on each system. Application for admission to this scheme should be made to the Industrial Collaboration Office at Harwell, from which further details may be obtained.

Medical School at the University College of Rhodesia and Nyasaland

The University College of Rhodesia and Nyasaland has appointed a planning committee to advise the College on the establishment of a medical school, and the committee will make a preliminary visit to the Federation of Rhodesia and Nyasaland next January. The committee's terms of reference are: "To advise the University College of Rhodesia and Nyasaland on the desirability and practicability of establishing a medical school as an integral part of the College; to prepare proposals for the training curriculum, postgraduate training, the research facilities, the buildings, equipment and staffing required, including those required for a suitable teaching hospital and other centres for clinical facilities; to prepare estimates of the capital and recurrent costs involved and a phased time-table for development; and to make any other proposals and suggestions for the development of medical education and research under the auspices of the College". The members of the committee are as follows: L. Farrer-Brown, director of the Nuffield Foundation (*chairman*); Prof. W. Melville Arnott, William Withering professor of Medicine, University of Birmingham; Prof. T. H. Davey, Middlemass Hunt professor of tropical hygiene, University of Liverpool; Prof. A. D. M. Greenfield, Dunville professor of physiology, The Queen's University of Belfast; Prof. P. B. Medawar, Jodrell professor of zoology, University College, London; Prof. R. Milnes Walker, professor of surgery, University of Bristol; and the Hon. Honor M. V. Smith, May reader in medicine, University of Oxford.

University Foundation of Brussels: Report for 1954–55

The thirty-fifth annual report of the University Foundation of Belgium, covering the year 1954–55 (pp. 153. Bruxelles: Fondation Universitaire), records that the Foundation made grants to 242 first-year students (of whom 45 were women), 561 to students in their second or subsequent years (105 women) and 971 grants were renewed (163 women). Of these grants, which totalled 5,843,000 francs, the great majority were at the Universities of Brussels (308), Ghent (331), Liège (269) or Louvain (653), the remainder being distributed among some fourteen other institutions, and all but thirty-six were for 3,000 francs. Students of medicine (469) received the largest number of grants, the next being engineering (253), philosophy and letters (242), science (241), commercial sciences, economics and finance (171) and law (165). Over the period 1930–55, 81 per cent of the grants were totally reimbursed. Some travel grants were awarded in 1954–55, and subsidies for scientific works and periodicals amounted to 1,984,000 francs, of which 1,559,500 francs was for periodicals. Subsidies to scientific or university associations amounted to 541,000 francs, and the report includes a list of institutions with which the Foundation has arranged the exchange of publications during the academic year and also a list of periodicals of which the Foundation has guaranteed a regular service to the scientific libraries of Belgium. In addition, statistics are included for the universities and high schools of Belgium. The number of students was 38,498, compared with 35,689 in 1953–54, and of these, 22,299 were pursuing courses in ancient humanities and 16,199 courses in modern humanities. Only 1,789 men and 646 women were taking science courses, 5,657 men and 1,152 women taking medicine or pharmacy, and 2,621 men and 20 women taking applied science, arts or manufactures.

Natural Resources, Food and Population in Inter-Tropical Africa

The International Geographical Union has published, under the title "National Resources, Food and Population in Inter-Tropical Africa", a report of a symposium held at Makerere College, Kampala, during September 10–17, 1955, with the financial support of the United Nations Educational Scientific and Cultural Organization (pp. 104. Bude: Geographical Publications, Ltd.; also Department of Geography, Makerere College, P.O. Box 262, Kampala, Uganda, 1956; 5*s*.). The president of the Union, Prof. L. Dudley Stamp, explains in a foreword that the symposium was designed to bring together workers in one of the major under-developed regions of the world and to concentrate on a study of the problems of the region. The report outlines the programme and gives the membership of the symposium, as well as summaries of the twenty-one papers read, but not of the discussions. These papers include a geographical appraisal of Buganda, by Prof.

S. J. K. Baker; Prof. L. D. Stamp's account of the World Land Use Survey in relation to intertropical Africa; land use surveys in the Sudan (Prof. J. H. G. Lebon); the physiography of south-central Uganda (J. W. Pallister); Kampala: planning background (H. Kendall); the division pattern of African agriculture in the Nyanza Province of Kenya (H. Fearn); the moisture resources of Nigeria and their utilization (Prof. B. J. Garnier); the strip fields of Southern Nigeria (W. B. Morgan); some aspects of food production in the Gold Coast (H. P. White); two types of agriculture in West Africa: their importance from the point of view of utilization of the soil (Prof. O. Ribeiro); the population of the Gold Coast (T. E. Hilton); population patterns and migrations in Sokoto Province, Northern Nigeria (R. M. Prothero); some aspects of irrigated agriculture in the Northern Province of the Sudan (Ahmed El-Sayed Osman); and the functional classification of settlements (Prof. M. Boesch). The symposium provided an invaluable opportunity for exchange of views and experiences of workers in contrasted parts of tropical Africa, and Prof. Stamp pays a warm tribute to the contribution which the work of Prof. S. J. K. Baker and his staff in the Department of Geography at Makerere College made to the success of the meeting.

Handbook on the International Exchange of Publications

THE second edition of the "Handbook on the International Exchange of Publications", edited and revised by Dr. Gisela von Busse, with the collaboration of Dr. H. Werhahn (pp. 5707. Paris: Unesco, 1956. 1,800 fr.; 36s.; 7 dollars), differs considerably from the arrangement and lay-out of the edition distributed in 1952. All addresses and references are now grouped in Part 2, which is in two sections, the first listing exchange offers of international organizations and the second outlining national exchange activities in eighty-four countries and thirty-seven territories. This section is arranged in the form of a directory and has been brought up to date as far as 1954 where the information was available. In both these sections entries are in English, French and Spanish, but Part 1 of the handbook is printed separately in English, French and Spanish. The first two chapters of this part describe the different forms of exchange and the way they are handled, including new sections on the publications of international organizations and on the exchange of the Organization for European Economic Co-operation. The third chapter, dealing with conventions and agreements for the exchange of publications, includes select lists of recent bilateral agreements for the exchange of official publications and of recent bilateral cultural agreements containing clauses referring to the distribution or exchange of publications. Like the fourth chapter, dealing with transport and customs, it essentially brings up to date the chapter in the first edition dealing with this subject. The lively demand for the first edition has shown that the handbook meets a real demand, and in its new form it should meet that demand even more effectively.

The Acquisition of Industrial Skills

EXPERIMENTS by W. D. Seymour on the acquisition of skills by operatives using capstan lathes showed that significantly better results were obtained with a part method of training only when the task contained elements which were perceptually stringent. Further experiments have now been devised to show whether such improved results arose from the use of the 'progressive part' method or whether equally good results would be achieved by merely isolating the perceptually stringent elements and training these before the whole task was attempted (*Occupational Psychol.*, 30, No. 2; April 1956). The learners were six boys and nine girls aged between 15½ and 18 years; all, except one, came from secondary modern schools. None had previous experience of the job chosen for the researches. They were separated at random into three groups, each of which was taught in a different way. One was shown the whole series of operations on a capstan lathe and then practised it as a whole until it could be carried out correctly in a given time. Another group, spending the same total time on learning and practising, did not tackle all the operations until it had practised first one and then a second particularly difficult operation, and could do each quickly and correctly in isolation. The third group, having the same time to learn, practised each operation separately, then combinations of some of the operations and finally the whole series. The first group was found to learn more slowly than the others; but there was no great difference in the time taken by the second and third groups. These results provide further evidence that the primary difficulty in acquiring speed skills in industrial tasks lies in the perceptual rather than the motor field.

Early Palæolithic Sites of Markkleeberg, near Leipzig

A PUBLICATION by the American Philosophical Society on "The Lower Palæolithic Site of Markkleeberg and other Comparable Localities near Leipzig" (*Trans. Amer. Phil. Soc.*, New Series, 45, Pt. 6 (1955); pp. 509–688; 2 dollars), by Rudolf Grahmann, is an account of the early Palæolithic sites of Markkleeberg that is of especial importance as the collections on which it is based were largely destroyed during the Second World War. One can no longer consider cultures as universal, even those occurring as early as Lower Palæolithic times. Already there were provinces where different cultures existed, and a different succession came about. The coup de poing culture, for example, occurs from South Africa to Western Europe, but scarcely exists east of the Rhine, where its place is taken by various cultures the tools of which were made from flakes instead of from cores. It is a commonplace that every generation likes to disprove the ideas of their forbears, and the Rhine frontier hypothesis has been recently criticized; but the present publication entirely backs it up. Only one coup de poing has been found among thousands of tools, and it was so poorly fashioned (judging by the illustration) as to be scarcely worthy of the name. All the tools found were made on flakes, and the industries are to be classed as flake-tool industries. Rudolf Grahmann comes to the conclusion that, geologically speaking, the industries that have been found date to the Mindel–Riss and to the Riss–Würm interglaciations. The earlier of these may well be the period of the famous Mauer jaw. Almost all the artefacts found are made from Baltic flint transported to the Leipzig region by the Mindel ice. Some of the material is grey and some of it black. The collections are classified, and a number of distinct types of tools and flakes distinguished. About half the publication is devoted to descriptions and to the illustrations, which are well drawn and give an excellent impression of the industries. The author is to be congratulated, and Dr. Hallam L. Movius, jun., who edited it, and the American Philosophical Society are to be thanked for the production of a very important publication which fills a gap in our knowledge of early Palæolithic cultures in the Leipzig region.

A Barking Crayfish

AN unusual example of a 'barking' crayfish has been reported from Newcastle, Australia (*Austral. Mus. Mag.*, 12, No. 2). Only one other example of the species (*Linuparus trigonus*) had previously been recognized around the Australian coastline; that specimen was also collected in seas adjoining the temperate eastern quarter of the continent and as recently as 1949. Both occurrences are surprise distributions of a crayfish which belongs to the Japanese seas. The strange noise made by the species has probably passed unnoticed until it was heard by Athol D'Ombrain as a harsh, grating noise. Its source was not located until some time after the death of the Newcastle specimen. Finally it was traced to the inner angles of the heavy basal joints of the stubby antennæ, immediately in front of the eyes. Here there are two smooth-lined cavities which enclose and bear upon a pair of highly polished bosses when the antennæ assemblage is thrown backwards over the head. Even after death a semblance of this friction-produced sound could readily be achieved by hand manipulation. The purpose of the 'barking' is not clear.

Zoological Nomenclature

THE International Commission on Zoological Nomenclature gives notice that as from December 26, 1956, it will start voting on the following cases involving the possible use of its plenary powers for the purposes specified against each entry. Full details are given in the *Bulletin of Zoological Nomenclature* (12, Pt. 3): (1) *Lepidurus* Leach, 1819, validation; *Triops* Schrank, 1803, determination of gender and designation of type species for (Cl. Crustacea, Order Decapoda); (2) Apodinae Hartert, 1897, (Cl. Aves), validation; (3) *volvulus* (emend. of *volvulas*) (*Filaria*), validation of, as from Leuckart, [1892] (Cl. Nematoda); (4) *Asaphus* Brongniart, 1822, validation of and designation of type species for; *cornigerus* Schlotheim, 1820 (*Trilobites*), suppression (Cl. Trilobita). Comments should be sent as soon as possible to Francis Hemming, Secretary to the Commission, 28 Park Village East, Regent's Park, London, N.W.1.

Cytogenetics and Breeding of Sugar-Cane

THE improvement of sugar-cane (*Saccharum officinarum*) by breeding and selection is of comparatively recent origin. Much work, however, is now going on in different tropical regions. T. S. Raghavan (*Proc. Indian Acad. Sci.*, 43, B, 2, 100; 1956) has pointed out that although the main aim in breeding work is to obtain high-yielding commercial cane, breeding for resistance to diseases is of great importance in some regions. Hybridization of different species of *Saccharum*, and sometimes of different related genera, has been necessary to obtain strains well suited to the needs of different regions. Where cane develops under favourable conditions, the noble (*S. officinarum*) and highly nobilized varieties have given good results as parents, while in less favourable areas *S. spontaneum* and *S. barberi* have given more satisfaction. At Coimbatore, *S. spontaneum*, and in Florida *S. robustum*, have proved of value in breeding programmes. Important intergeneric crosses are those with bamboo and *Sorghum*. Sugar-cane as a breeding material is fundamentally different from other commercial crops. It is a highly heterozygous polyploid complex with a large reserve of lethal genes which, especially in *S. officinarum*, are responsible for there being practically no survivals in the selfed progeny. It is only clonal propagation that has made it survive. Arising mainly out of its genetical impurity and high allopolyploidy, no prediction can be made as to the nature of the progeny to be expected in a cross. The high heterozygosity of the chromosomal material of both the parents renders odds against anticipating any desired combination. The occurrence of parthenogenesis and of chromosome elimination has raised new issues which are now recognized in the cytogenetic approach to practical problems. Lists of crosses and of parental and hybrid chromosome numbers are given.

Use of Silage in British Agriculture

FERMENTED green fodder has now come to be recognized as a valuable supplement to the traditional roots and hay for winter feeding of cattle. It also fits in admirably with the present-day intensification in Britain of grassland management based on increased use of fertilizer. It is therefore important that the facts concerning silage making and use should be brought thoroughly up to date and presented in a clear practical manner together with just enough of the theory to make the rules comprehensible. This task has been admirably carried out by a group of officers of the National Agricultural Advisory Service and published as a revision (the seventh) of Bulletin No. 37, "Silage", of the Ministry of Agriculture (pp. 58 + 1 plates. London: H.M.S.O., 1956. 3*s.* net). Silage, properly made, has a feeding value about twice that of roots and rather more than that of hay, reckoned on a starch-equivalent basis. It is readily eaten by cattle, and fortunately many of the operations of growing, cutting, carting and making lend themselves to mechanization, an aspect of the subject which rightly occupies an important place in the treatment. Grass is not the only crop suitable for silage making, though it is the most important; the use of arable crops, including by-products such as sugar-beet tops, is dealt with. The addition of extra carbohydrate as molasses to high-protein crops in order to secure a favourable fermentation is also explained. On the national level, any farming practice which can reduce the expensive imports of concentrated feeding stuffs into Britain deserves official encouragement. To put the facts before farmers is clearly a step in the right direction.

A Survey of Atomic Energy

THE spring issue of *Studies*, the Irish quarterly review, contains an interesting article entitled "Atomic Structure and Atomic Energy", by Prof. T. S. Wheeler, professor of chemistry in University College, Dublin, in which he gives an excellent summary of our present knowledge of the structure of the atom and the production of atomic energy. The component parts of the atom, isotopes, the relationship between matter and energy, nuclear fission, the uranium and plutonium bombs, nuclear reactors, and the British programme of nuclear power are all described briefly but adequately. The hydrogen bomb receives rather scanty treatment. So many technical terms are used throughout the article that one would have thought the term 'thermonuclear reaction' would have also been mentioned. Radioisotopes and their numerous uses are not mentioned. The article will be most useful to those who are fairly well acquainted with basic physics and chemistry, and will serve admirably as basic notes for lecturers on the subject of atomic energy. Quotations from recent utterances of the Pope on the terror of atomic destruction and on the wonderful results of the applications of atomic energy in the industrial, biological and medical spheres preface and conclude the article, respectively.

Production of Single Crystals of Germanium

The zone-melting technique employed for the production of metals of very high purity has been modified by D. C. Bennett and B. Sawyer (*Bell System Tech. J.*, 637 ; May 1956) for the production of single crystals of germanium of exceptional crystalline perfection and uniformity of composition. The apparatus as described can produce crystals up to 6 in. long in which the average variation of resistivity along the length can be controlled to ± 7 per cent, while the variation over the cross-section can be as low as ± 3 per cent. The crystals contained no grain boundaries or twins, and the etch-pit densities, used as a measure of the number of dislocations, average about 1,500/sq. cm., though much lower values than these have been obtained, the lowest as yet observed being 40 pits/sq. cm. The variation of composition as measured by the resistivity is principally due to variations of the volume of the liquid zone due to temperature fluctuations, variations in the rate of flow of inert gas and cracks in the unmelted charge. The temperature gradients at the melting and freezing surfaces are important, the former being 130 deg. C./cm. and the latter about 10 deg. C./cm. The rate of growth of the crystal—that is, the rate of traverse of the boat through the furnace—affects its quality, a rate of about an inch in three hours being reasonable where the best results are required.

National Museum of Canada : Report for 1953–54

The annual report for 1953–54 of the National Museum of Canada which has recently been published as Bulletin No. 136 of the Museum (pp. 122+16 plates. Ottawa: Queen's Printer, 1956; 1.50 dollars) prefaces an account of the general activities of the year with a restatement of its main functions. These are: "to collect and preserve Canadian anthropological and natural history material of scientific or economic interest; to carry out studies in connection with this material; and to provide and disseminate information regarding natural science and ethnology by means of exhibits, publications, lectures and photographs". The illustrated report fully justifies the claim of the Trustees that the Museum is carrying out the functions for which it was founded, for, in addition to the usual accounts of curatorial work, original papers by the staff on related subjects are published. A new venture was initiated when a bronze plaque was erected by the Museum at Hogsback, near Ottawa, to explain the geology of this interesting locality. This is the first attempt to mark a scientific site in Canada and could with advantage be followed in Great Britain.

Calendar Reform in India

The Calendar Reform Committee, which was set up some years ago by the Government of India, has reported on its work of examining the different calendars of India (pp. 280, published by the Council of Scientific and Industrial Research, Old Mill Road, New Delhi, 1955; n.p.). At the present moment, thirty calendars are in use in India, each of which differs from the others in various ways, including the methods of time reckoning. While these are the natural results of India's past political and cultural history, representing to some extent political divisions, now that India has attained independence uniformity in the calendar is desirable. The Gregorian calendar is followed by India, as it is in the greater part of the world; but many countries have found that, in spite of its virtues, it has its defects, and the present report gives the results of the Committee's recommendations, in addition to a large amount of useful information on various astronomical matters. In the unified national calendar, it is proposed that the Śaka era should be used, the year 1954–55 corresponding to 1876 Śaka, and a year would consist of 365 days with the usual arrangements for leap-years. The first month of the year would be Caitra, which would contain 30 days, or 31 in leap-years, and Caitra 1 would correspond to March 22 in the Gregorian calendar, or March 21 in a leap-year. The months following Caitra are Vaisākha, Jyaistha, Asādha, Śrāvana, Bhādra, Asvina, Kārtika, Agrahāyana, Pausa, Māgha, Phālguna; the first three would contain 31 days each, the next three in order 31, 31 and 30 days, and the next five 30 days each. The dates of the reformed Indian calendar would thus have a correspondence with the dates of the present Gregorian calendar, and, starting with Caitra, the months following in the order given above would correspond with April 21, May 22, June 22, July 23, August, 23, September 23, October 23, November 22, December 22, January 21 and February 20. In addition to recommendations for religious calendars, it is suggested that an "Indian Ephemeris and Nautical Almanac" should be compiled which, besides showing the positions of the heavenly bodies, should include the Indian calendar—both civil and religious—prepared according to the recommendations of the Committee.

The Night Sky in September

New moon occurs on Sept. 4d. 18h. 57m., U.T., and full moon on Sept. 20d. 03h. 19m. The following conjunctions with the Moon take place: Sept. 1d. 12h., Venus 1° N.; Sept. 6d. 17h., Mercury 0·8° N.; Sept. 10d. 07h., Saturn 2° N.; Sept. 19d. 14h., Mars 11° S. In addition to these conjunctions with the Moon, Venus is in conjunction with Pollux on Sept. 2d. 15h., Venus being 9·5° S. Mercury is too close to the Sun for observation. Venus rises at 1h. 15m., 1h. 30m. and 2h. 00m. on September 1, 15 and 30 respectively, and is a bright object with magnitude varying between −3·9 and −3·7, the visible portion of its illuminated disk increasing from 0·503 to 0·641; during this time its distance from the Earth increases from 57 to 86 million miles. Mars rises at 19h. 40m., 18h. 35m. and 17h. 25m. at the beginning, middle and end of the month, respectively, the corresponding times of setting in the morning being 6h. 10m., 4h. 50m. and 3h. 35m.; its stellar magnitude varies between −2·6 and −2·3 and its distance from the Earth is a minimum on September 7, being 35 million miles and increasing to 39 million miles by September 30. Mars is a little east of ψ Aquarii, and this opposition is particularly favourable for observers because it occurs near the perihelion of Mars. Jupiter is too close to the Sun for observation during the early part of the month; it rises at 4h. 10m. on September 30, almost two hours before the Sun, and is near σ Leonis. Saturn sets at 21h. 25m., 20h. 30m. and 19h. 35m. on September 1, 15 and 30, respectively, and is approaching β Scorpii during the month; its stellar magnitude is 0·7, and its distance during the middle of the month is about 960 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich (*D* and *R* refer to disappearance and reappearance, respectively): Sept. 13d. 20h. 28·8m., 29 Sgr. (*D*); Sept. 27d. 00h. 03·6., χ^1 Ori. (*R*); Sept. 30d. 02h. 39·5m., 60 Cnc. (*R*). The autumnal equinox occurs on Sept. 23d. 02h.

Announcements

THE following have been appointed to chairs in the newly established Medical School in the University of Western Australia: *Biochemistry*, Prof. J. W. H. Lugg, professor of biochemistry in the University of Malaya and formerly of the University of Melbourne; *Physiology*, Dr. W. J. Simmonds, of the Kanematsu Memorial Institute of Pathology, Sydney Hospital, and formerly lecturer in physiology in the University of Sydney; and *Pathology*, Dr. R. E. J. ten Seldam, reader in physiology in the University of Sydney and formerly director of pathology of the Roman Catholic Hospitals, Eindhoven.

IN view of the diversity of the programme, both geographically and scientifically, of the International Geophysical Year, 1957–58, the bureau of the special committee of the International Council of Scientific Unions decided to appoint a full-time officer to assist in the co-ordination of the operations in order to ensure that the Year achieves its fullest promise. Vice-Admiral Sir Archibald Day, hydrographer of the Royal Navy during 1950–55, has been selected for this post of co-ordinator of operations, and he will have his office in Brussels alongside that of the general secretary. Since his retirement, Sir Archibald, who is fifty-seven years old, has been on a hydrographic survey of Lake Nyasa, and the Ministry of Transport and Communications in the Federal Government of Rhodesia and Nyasaland has agreed to release him in order that he may take up his new post.

J. R. PUGH, assistant to the chief traction engineer of British Insulated Callender's Construction Co., Ltd., has been awarded the Sir Alexander Roger travelling scholarship for 1956 and will visit Germany, Austria, Sweden and France to study the design, erection and performance of high-voltage a.c. traction equipment. Since joining the Company in 1948 as a graduate apprentice from the University of Cambridge, Mr. Pugh has worked on the technical aspects of railway electrification schemes. This scholarship has been established by British Insulated Callender's Cables, Ltd., as a tribute to Sir Alexander Roger, its first honorary president.

THE British Oxygen Co., Ltd., has awarded fellowships for postgraduate research to C. M. George (Department of Chemistry, University of Bristol) and N. G. Parsonage (Inorganic Chemistry Laboratory, University of Oxford). The fellowships of the following have been renewed for a third year: B. F. Figgins (Queen Mary College, London), D. H. Kirkwood (Department of Metallurgy, University of Cambridge) and R. D. McCammon (Clarendon Laboratory, University of Oxford).

AN informal discussion on "Nucleic Acids and Nucleo-Proteins: Structure and Function" will be held under the auspices of the Colloid and Biophysics Committee of the Faraday Society during October 12–13 at the Manson Hall of the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1. About twenty papers will be read. The accommodation is limited, but those who would like to attend are invited to communicate with Dr. K. V. Shooter, Chester Beatty Research Institute, Fulham Road, London, S.W.3, from whom further information can be obtained.

THE Photobiology Group will hold a meeting in the Botany School, Downing Street, Cambridge, during September 28–29, under the chairmanship of Dr. M. H. Pirenne. The annual general meeting of the Group will be held on the second day. Non-members of the Group can participate on payment of a fee of 5*s*. Further information can be obtained from Dr. R. Hill, Biochemistry Department, Tennis Court Road, Cambridge.

THE ninety-ninth meeting of the Gesellschaft Deutscher Naturforscher und Ärzte will be held in Hamburg during September 23–26. On the first day, prior to the meeting proper, a discussion will be held on science and the general educational programme of German high schools. Further information on the whole meeting can be obtained from Dr. Weber, Sekretariat der Gesellschaft Deutscher Naturforscher und Ärzte, Hamburg-Harburg, Phönix-Gummiwerke A.G.

THE Hungarian Scientific Society for Measurement and Automation is organizing a conference, to be held in Budapest during October 1–4, at which the following eight topics will be discussed: general features of instrumentation, metrology and nomenclature; mechanical measurements; optical measurements; thermodynamics; communications measurements; physico-chemical measurements; nuclear radiation measurements; and mathematical instruments and machines. Most of the papers will be in Hungarian, but translations in English and German will be available in advance. Papers from abroad are invited; these should be not more than twenty minutes in reading time and should be in English, French, German or Russian. Shortened versions, of 500–800 words in length, must be sent before September 1. Further information can be obtained from the Secretariat, Hungarian Scientific Society for Measurement and Automation, Budapest V, Honvéd-u.22.1.3.

THE British Memorial Fund of Victoria, Australia, is offering a further four fellowships for 1957 to British subjects, less than thirty-five years old, with at least ten years of residence in the United Kingdom. Two of the fellowships are in natural history and chemical engineering, respectively, and two are open for any choice of study or research. Each is worth £A1,000 and tenable only in Victoria. Application forms, to be completed by September 15, and further information can be obtained from the Victorian Agent-General in London, Colonel the Hon. W. W. Leggatt, Victoria House, Melbourne Place, Strand, London, W.C.2.

SECOND INTERNATIONAL CONGRESS ON ACOUSTICS, CAMBRIDGE, MASSACHUSETTS

THE Second International Congress on Acoustics, sponsored by the International Commission on Acoustics, was combined with the regular summer meeting of the Acoustical Society of America and was held in Cambridge, Massachusetts, during July 17–23, with support from Unesco and the U.S. National Academy of Sciences, and with the Massachusetts Institute of Technology and Harvard University acting as hosts.

The opening ceremony consisted of a reception of participants by the sponsoring bodies. Later, as relaxations from the technical programme, there were a sight-seeing tour, a concert and a banquet. An exhibition of books and instruments dealing with acoustics was held at Harvard. Of interest even to non-technical members of the Congress was a symposium on musical and architectural acoustics held in the Sanders Theatre of the University, where W. C. Sabine made his first measurements of reverberation time in 1895. At this symposium Prof. V. O. Knudsen showed some relics of the famous cushions, which Sabine bought up from a church that was then being refurnished and which he compared in absorbing power with an open window. Other symposia covered the subjects of bio-acoustics and noise control, speech analysis and physical acoustics. In addition, about a score of technical sessions were held involving some four hundred authors of papers and covering between them all branches of the subject, both pure and applied.

It is impossible in a reasonable space to refer to all these; but an attempt will be made to indicate those aspects of the subject which seem to be enlisting the greatest attention and showing most significant advances.

What may be called 'visco-elasticity' or 'relaxation spectrometry', according to the interests of the experimenter, continues to be a fruitful subject both in sonics and ultrasonics. The variation of absorption of sound waves with frequency and—in the case of gases—of velocity of sound with frequency continues to provide the physical chemist with valuable data, which are proving of use also to the metallurgist, to the maker of plastics and—in respect of relaxation in vapours—to the aerodynamicist.

In this age of jet propulsion, measurements and calculations by physicists and engineers on the production of noise from a transonic or supersonic jet of gas emerging from a nozzle are numerous; so, too, are the considerations of the sounds in boundary layers and the propagation of sounds through the atmosphere, particularly when it is turbulent. In one paper mention was made of the sounds of underwater jets. Does this mean that the ship designer is returning to a mode of propulsion which he abandoned in 1885?[1].

Noise was, of course, apart from this special field, much discussed—in buildings, in traffic and in machinery—especially in relation to its psychological and physiological aspects.

The sessions dealing with speech and music showed a comparatively small number of research workers, many using such time as they can spare from more urgent acoustical work, and treading a rather pedestrian track of analysis and synthesis; but the number of people interested in this field seems to be increasing. The need here seems to be for more inspiration.

Authors of papers were invited to submit them for publication in the *Journal of the Acoustical Society* or in *Acustica*. The meeting was highly successful and attracted more than twelve hundred registered members, undoubtedly the largest number of students and exponents of this field of physics ever brought together. At the concluding session, it was announced that the Third International Congress would be held in Stuttgart in 1959.

COMPARATIVE MARINE BIOLOGY

CONFERENCE IN ROSCOFF

AT the International Congress of Zoology held in Copenhagen in 1953, members of the Zoology Section of the International Union of Biological Sciences proposed to the general assembly that a meeting should be held in 1956 to discuss the comparative biology of aquatic species throughout the area of their distribution. The plan was approved; the meeting, under the auspices of Unesco, and limited to the discussion of marine and brackish-water species, was held during June 27–July 4 at the Station Biologique, Roscoff, at the invitation of Prof. L. Fage, Prof. G. Teissier and Prof. P. Drach; the last was responsible for the organization. Prof. S. O. Hörstadius, president of the International Union of Biological Sciences, was present, together with biologists from fourteen countries.

The plan of the meeting was twofold. First, by means of papers and discussions to review various aspects of the problems involved in understanding the distribution of species—the disciplines and approaches of the general biologist, the ecologist, the physiologist and the geneticist are all essential and complementary in this field of work. Secondly, to initiate new co-operative efforts—the possibilities of exchange of workers, co-operative schemes of work on selected species, and standardization of techniques were to be considered.

The papers were divided into groups; under the general heading of "The Biological Cycles of Marine Organisms", the biology of *Ostrea edulis*, *Mytilus* sp., *Calanus finmarchicus*, *Carcinides moenas*, and *Nereis* sp. were considered in relation to their geographical range. Two papers dealt with algal distribution. Morphological variation and biometrical studies were introduced in a general paper by Prof. Teissier, and this was followed by communications dealing with intestine length in Clupeoid fishes, differences in widely separated populations of *Gobius minutus* and a general consideration of meristic characters of fishes in relation to temperature and water movements. The third group of papers dealt with the inter-relation of temperature and salinity with the distribution and metabolism of marine animals as well as the more general aspects of respiration, temperature adaptation and physiological variation.

Genetical constitution and distribution formed the subject of the fourth group. The general impression gained was that, although for some species much is known regarding the response to environmental stresses over the area of distribution, a great deal remains to be done before any general principles can be formulated. Progress in this direction will come only from a concerted attack by all available techniques on the biology of a few selected and representative species that are able to live throughout a wide latitudinal range or in a wide variety of environmental conditions. To this end, the conference resolved that the attention of appropriate bodies should be directed towards increasing the number of permanent positions in marine laboratories, and to the provision of technical personnel so as to permit a world-wide programme of continuous records of a physical, chemical and biological nature to be established. Collaboration with existing bodies devoted to marine science was recommended, and furtherance of international co-operation by the support of fellowships, travel, meetings and an information service was suggested.

The problems arising in the organization of co-operative research were discussed in two general papers and also by the conference sitting in committees. Divergent opinions were revealed. It was felt by some that for real progress some of the work should be in the hands of a limited number of specialists with security of tenure and at the same time freedom to move from place to place. Others felt that much could be done with the expansion of facilities for individual workers within the framework of existing institutions. Certainly the latter has more chance of immediate attainment. To this end a resolution was passed urging the importance of investigations of the biology of marine species throughout their geographical range; it was further recommended that institutes should be encouraged to set up programmes of continuous collection of basic information and that a means for its distribution should be established. The importance of publishing fauna and flora lists was emphasized; lists of common species, and if possible their breeding seasons and abundance, would be most valuable.

It was recommended that a small committee should be set up to further the objects and resolutions of the conference.

H. BARNES

BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

RESEARCH PANEL MEETING

THE twelfth meeting of the Research Panel of the British Gelatine and Glue Research Association was held on June 7, with Mr. S. G. Hudson (Richard Hodgson and Sons, Ltd.) in the chair. Two papers were presented, each by members of the staff of the Association, during the morning session, and both were followed by lively discussion. In the afternoon the Association's laboratories at 2*a* Dalmeny Avenue, London, N.7, were open for informal discussions.

The first paper, by Dr. A. Courts, on the collagen–gelatin transformation, described a series of fundamental investigations into the changes which occur during the pretreatment and extraction of collagenous material such as hide and ossein (demineralized bone). Both type and intensity of pretreatment influence the degree to which the extraction stage can be regarded as a 'melting out' of already preformed gelatin. In the normal industrial processes some further hydrolytic reactions are known to occur, especially during the later stages of extraction. One tool of which extensive use was made was the technique of Sanger[1], in which reaction between amino-groups and 1-fluoro-2 : 4-dinitro benzene gives, after hydrolysis and chromatographic separation, the number of α-amino-groups in a protein. Since these groups terminate polypeptide chains, the average chain-length can be obtained from this figure. Ossein, after treatment for periods of between two weeks and six months with a suspension of calcium hydroxide in water at 20° C., was found to reach rapidly the stage at which the average chain-length in the treated ossein could be related to that of the gelatins which could be obtained from it. The residue left after each extraction of gelatin by hot water had a chain-length which remained substantially constant. It may be presumed that all slightly shorter chains produced by hydrolysis went into solution as gelatin. The diphenylamine method of Anderson and Maclagan[2] was used to estimate mucoprotein at all stages of the process. The action of lime in removing this group of substances was clearly shown.

Dr. Courts also described the successful preparation of gelatin without the use of heat. Raw material which had received alkaline pretreatment was extracted by strong solutions of hydrogen bond-breaking agents, at room temperature. A substantial proportion of the material passed into solution as good-quality gelatin. This shows clearly that at late stages of pretreatment the raw material is primarily held together by hydrogen bonds.

The second paper, on the molecular weights of some gelatin fractions by the light-scattering method, was by Dr. A. Courts and Dr. G. Stainsby, and was read by the latter. He described briefly the technique used in measuring the light scattered by dilute gelatin solutions at 40° C., and also how the weight-average molecular weight (M_w) can be deduced from this. He then described the method[3] which has been developed to allow for the light scattered by the small quantities of suspended particles present in the solutions. These, which are of a non-gelatin nature, remained to some extent even in the most carefully purified solutions. After measuring the light scattered from the gelatin solution, a small addition of a solution of crystalline trypsin rapidly reduced the size of the gelatin molecules to a level at which they scattered only negligible amounts of light. The residual scatter at this stage was due to the solvent and to the suspended impurities. Measurement of its intensity enabled the scattering due to gelatin to be obtained, by subtraction, from the scattering figures for the original gelatin solution. Only by developing this technique was it possible to get reliable figures for gelatin weight-average molecular weights.

Two series of fractions, one of an alkali-processed gelatin (first extraction) and the other of an acid-processed gelatin (also first extraction), were examined by the method of light scattering for M_w, and by the Sanger end-group technique for C_n (the number-average chain-length). The results for the alkali-processed material are given in Table 1.

Table 1

Fraction	M_w	C_n
2	270,000	55,000
3	142,000	70,000
4	74,000	70,000
5	57,000	70,000

If the gelatin molecule consisted of a single polypeptide chain, it would be expected that M_w and C_n would only differ slightly, owing to imperfect fractionation. The very large differences observed may be interpreted as indicating that the gelatin molecules of higher molecular weight are composed of some half a dozen chains covalently linked in some way. It seems likely that these linkages have their origin in the collagen and are not produced in the conversion of collagen to gelatin.

Refractionation has been used to show that the extreme heterodispersivity needed to account for the results, if C was identical with M, is not the cause of the discrepancy. An examination of the F.D.N.B. reaction in the light-scattering cell has shown that the conditions used do not cause marked degradation while the reaction is in progress. There is, on the contrary, some indication of a cross-linking reaction. This would not interfere with the determination of the α-amino-groups.

Somewhat similar results to those with the alkali-processed gelatin were obtained with the acid-processed gelatin fractions. The situation was complicated by an indication that, at least for the lower molecular weights, the chains did not always terminate in an α-amino-group at one end.

INTERNATIONAL WHALING COMMISSION

EIGHTH ANNUAL MEETING

THE eighth annual meeting of the International Whaling Commission was held in London during July 16–20, all the seventeen contracting Governments, with the exception of Brazil, being represented. They were: Australia, Canada, Denmark, France, Great Britain, Iceland, Japan, Mexico, the Netherlands, New Zealand, Norway, Panama, South Africa, Sweden, the U.S.S.R. and the United States. Italy and Portugal were represented by observers, as were also the Food and Agriculture Organization of the United Nations, the International Council for the Exploration of the Sea and the International Association of Whaling Companies. Dr. G. J. Lienesch (Netherlands), chairman of the Commission, presided.

According to the figures compiled by the Bureau of International Whaling Statistics at Sandefjord, nineteen factory ships with 257 catchers were engaged during the 1955–56 Antarctic season, and the total catch by floating factories increased from 2,061,789 barrels to 2,134,012 barrels inclusive of sperm oil; there are six barrels to the ton, and the average price for whale oil is £70–80 per ton. The chief object of the Commission is to arrange a balance between killing- and replacement-rates of the whale populations, and to achieve this it sets limits upon the total catch. The limit takes into consideration the views of scientists upon the size of the stocks of whales and of the whalers on the economics of the industry, the scientific opinion being almost unanimously in favour of a substantial reduction in the catch on account of evidence that the stock is declining. The existing limit is 15,000 blue whale units, and the Commission recommended that the catch for future seasons should not exceed this amount, and it further recommended (with one dissentient) that the limit should be reduced during the coming 1956–57 season to 14,500 blue whale units.

Infractions of the whaling regulations during the past year were fewer than those of the previous year. At present every factory ship is required to have on board two inspectors who are generally of the same nationality as the flag of the ship. However, following the seventh meeting of the Commission in Moscow in 1955, the United States was asked to prepare a protocol for the amendment of the Convention so as to permit consideration of a scheme to appoint independent observers in addition to the national inspectors. All possible steps are now being taken to ensure that the protocol can be brought into force in time for the Commission to take action under its provisions at its ninth meeting, and it is hoped that the protocol will very soon be signed.

A statement of expenditure for the year ending May 31, 1956, amounting to £3,196, was approved by the Commission. For the current year due to end on May 31, 1957, the expenditure by the Commission is estimated at £2,935, and the contribution requested of each of the twelve contracting Governments remains at £150. £500 was set aside towards the cost of whale marking, which is the means of providing much of the essential scientific data on which the Commission's recommendations for the conservation of the whale stocks need to be based.

It was decided that a scientific sub-committee should again if necessary meet to consider certain scientific problems in anticipation of the next annual meeting, which will also be held in London, commencing on June 24, 1957.

THE B.B.C. AND ITS EXTERNAL SERVICES

A BOOKLET entitled "The B.B.C. and its External Services"*, describing the B.B.C.'s transmissions for listeners overseas, is of special interest at the present time in view of Sir John Glubb's recent convincing arguments that expenditure on the dissemination of ideas brings a higher dividend than expenditure on weapons. The booklet does not indicate what proportion of the B.B.C.'s income of £21 million from licence receipts (of which in 1955–56 the Government retained £2·75 million), £1 million from publications and £5·322 million from grants-in-aid was expended on external services; but these services in English and forty-three other languages are heard throughout the world, and occupy about eighty hours daily.

* The B.B.C. and its External Services. Pp. 32. (London: B.B.C. 1956.)

Thirty-nine high-power short-wave transmitters are used, of which two, for relay purposes, are operated at Tebrau, in Johore, by the B.B.C. Far Eastern Station. Medium-wave transmissions from Britain are largely confined to the radiation of those parts of the European Service broadcast to Western Europe throughout the evening on 224 m. Other long and medium wave-lengths are used when not required for the B.B.C.'s domestic services. Certain of the European Services are also broadcast by a high-power medium-wave transmitter at Norden in north-west Germany, with a medium-power relay in Berlin operating on the same wave-length, and are re-broadcast additionally over a very-high-frequency frequency-modulated transmitter in Berlin, where many suitable receivers are in general use.

To provide an effective signal in the area served by each programme, highly directional short-wave transmitting aerials are used, the appropriate aerial being selected from 177 aerials at the various transmitting-sites; but even this large number is insufficient to meet all propagation conditions. A continuous schedule of aerial conversion to different wave-lengths is required to ensure that programmes are radiated in the most easily receivable wave-bands, and this programme is designed to keep pace with the trend of solar activity. During the next four years the B.B.C. will make regular use of the higher-frequency bands for its external services, and wave-lengths in the 13-m. and 11-m. bands now serve large areas of South and South-East Asia, the latter band in particular providing transmission which escapes the severe interference affecting many of the external services programmes on the longer wave-lengths. Some of this interference is due to the overloading and unplanned operation of the bands allotted to short-wave broadcasting; but much of it is caused by deliberate interference (jamming) with certain language transmissions from the B.B.C. and from other countries. This jamming also affects the adjacent wave-lengths.

The Monitoring Service, which intercepts and reports foreign broadcasts, is an integral part of the External Broadcasting Organization. The B.B.C. has close ties with most of the forty-five broadcasting organizations in the British Commonwealth, and offices for B.B.C. representatives are maintained in Cairo, Delhi, New York, Ottawa, Paris, Sydney and Toronto.

THE SONIC GAS ANALYSER

By DR. A. E. MARTIN

Sir Howard Grubb, Parsons and Co., Ltd., Newcastle upon Tyne

ALTHOUGH efforts have frequently been made to develop a gas analyser depending on the variation of the velocity of sound with the nature of the gas, no practical instrument was produced until quite recently. The successful development of this gas analyser is due to the efforts of, among others, J. G. Dawes[1], J. H. D. Walton[2], L. E. Lawley[3], and D. Mounfield (Sir Howard Grubb, Parsons and Co., Ltd.).

The sonic gas analyser has certain advantages over some other types of instrument, the more important being: (1) no correction for variations in pressure is necessary since the velocity of sound is independent of pressure; (2) temperature compensation is easily arranged; (3) practically any mixture of gases can be dealt with; (4) the time lag can be made negligible; (5) the analysis unit is intrinsically safe and, since it can be placed at any distance from the measuring unit, can be used in refineries, coal mines and other places where an explosive atmosphere may be found; (6) it is possible to calculate to within a few per cent the sensitivity of the instrument and therefore actual calibration is unnecessary in many cases.

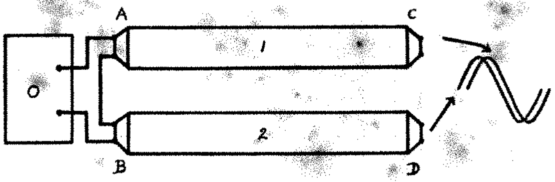

Fig. 1. Principle of the sonic gas analyser

Fig. 1 illustrates the principle of operation of the sonic gas analyser. A and B are sound transmitters, which for convenience may be deaf-aid magnetic earpieces, and these are actuated together by the oscillator O. Each transmitter is placed at one end of a tube and a similar earpiece is mounted at the other end of the tube to act as a microphone. If the distances A to C and B to D are equal, and both tubes contain the same gas, the time taken for sound to travel from A to C will be exactly the same as from B to D and the a.c. signals derived from the receivers C and D will be in phase. If now the gas in tube 2 is replaced by a heavier gas, for which the velocity of sound is lower, the signal received by D will lag behind that arriving at C by some angle θ, as indicated in Fig. 1. It is easy to see that

$$\theta = 2\pi f d \left(\frac{1}{V_2} - \frac{1}{V_1}\right) \tag{1}$$

where f is the frequency of the sound, d the distance from transmitter to receiver in either tube, and V_1 and V_2 the velocity of sound in tubes 1 and 2, respectively. By employing two tubes in this way temperature effects largely cancel out.

It is nowadays possible to measure θ by the application of electronic techniques, and in one particular instrument, for which $f = 3{,}000$ c./s. and $d = 30$ cm., full scale for a phase change of 20° is obtained.

To calculate the phase change to be expected for any given gas mixture, it is convenient to rewrite equation (1) by using the relation $V = \sqrt{\frac{\gamma RT}{M}}$, where γ is the ratio of the specific heats c_p/c_v, R the gas constant, T the absolute temperature and M the molecular weight. We then have:

$$\theta = \frac{2\pi f d}{\sqrt{RT}}\left(\sqrt{\frac{M_2}{\gamma_2}} - \sqrt{\frac{M_1}{\gamma_1}}\right) = 207\left(\sqrt{\frac{M_2}{\gamma_2}} - \sqrt{\frac{M_1}{\gamma_1}}\right)$$

in degrees for the values of f and d given above and for a temperature of 20° C. The variation of θ with temperature is approximately 1 part in 600 per 1° C. For most diatomic gases γ is close to 1·4 and then $\theta = 175°(\sqrt{M_2} - \sqrt{M_1})$. Thus for air ($M_2 = 28·95$) and nitrogen ($M_1 = 28$), $\theta = 15·6°$, which is nearly full scale on the standard instrument.

For 1 per cent by volume of an admixed gas or vapour in air the following simple relations can be derived:

$$\theta(\text{degrees}) = \frac{M}{6} - 3{\cdot}4\,\gamma \qquad (2)$$

$$\theta(\text{degrees}) = \frac{M}{6} - 6\left(1 - \frac{n}{10}\right) \qquad (3)$$

where M is the molecular weight, γ the ratio of specific heats and n the number of atoms per molecule of the 'impurity'.

Equation (2) is preferable for molecules containing only a few atoms, while (3) is more suitable for larger molecules. The values obtained for θ are in general accurate to a few per cent. [May 10

SLOW DECOMPOSITION OF EXPLOSIVE CRYSTALS

By Dr. F. P. BOWDEN, C.B.E., F.R.S., and J. McAUSLAN

Laboratory for the Physics and Chemistry of Surfaces, Department of Physical Chemistry, Cambridge

WHEN silver, lead, cadmium or other metallic azides are heated to a temperature below that necessary to cause detonation, they decompose comparatively slowly into metal and gaseous nitrogen. The kinetics of this decomposition, as determined from pressure/time curves, have been investigated by a number of workers[1]. A microscopic examination of the crystals during the process shows that they crack and split along crystallographic planes. The splitting can be violent, and it indicates that metal is formed and nitrogen liberated inside the crystal. There is evidence from some observations in the electron microscope (using a replica technique) that single crystals of lead or cadmium azide break up into small blocklets about 10^{-5} cm. across, and it has been suggested that reaction may occur preferentially at defects within the crystal[2]. The role of dislocations, impurity centres and crystallographic irregularities is not fully understood; but we may expect them to assist in the early stages of decomposition. Mitchell[3] has shown their importance in the decomposition of silver halides.

Sawkill[4], working in this Laboratory, has followed in the electron microscope the progressive decomposition of silver azide under the influence of the electron beam. At the same time, he used electron diffraction to determine the change in the atomic arrangement. The results show that the formation of crystalline silver is preceded by a migration of silver atoms into the azide lattice. The initial spacing of these silver atoms is wider than that of the normal silver lattice, but collapse occurs resulting in the formation of small single crystals of silver in the surface layer of the main azide crystal. In addition to this, and beneath it, a network of fine silver is observed which gives a ring pattern in electron diffraction and which may correspond to the liberation of silver on defects within the body of the crystal. Again the size of the units in this network is found to be about 10^{-5} cm. In these experiments the electron beam falling on the crystal induces chemical change. This can be due to the rise in temperature of the specimen or to the primary action of the high-energy electrons. There is evidence, in Sawkill's experiments, that the second factor is important.

A more direct attack on the mechanism of thermal decomposition has been rendered possible with the development by Oatley and his colleagues in the Engineering Laboratory at Cambridge[5] of a scanning electron microscope which can be used in reflexion or transmission. The electrons are focused to a narrow

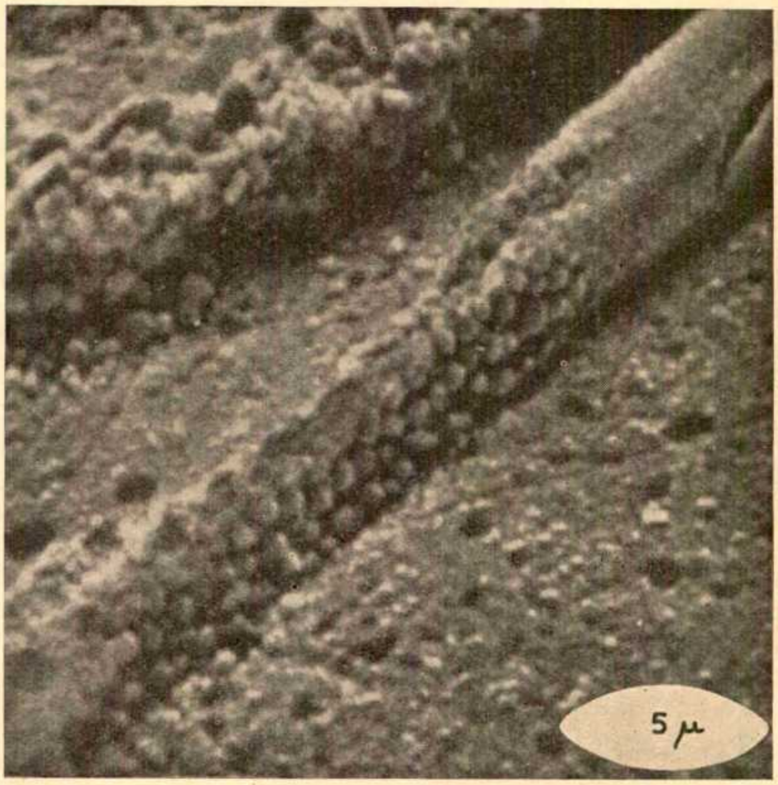

Fig. 1. Partly decomposed needle of silver azide of approximately 1μ cross-section. Decomposition has started from lower end, causing the needle to break up into blocks about 0·3μ across

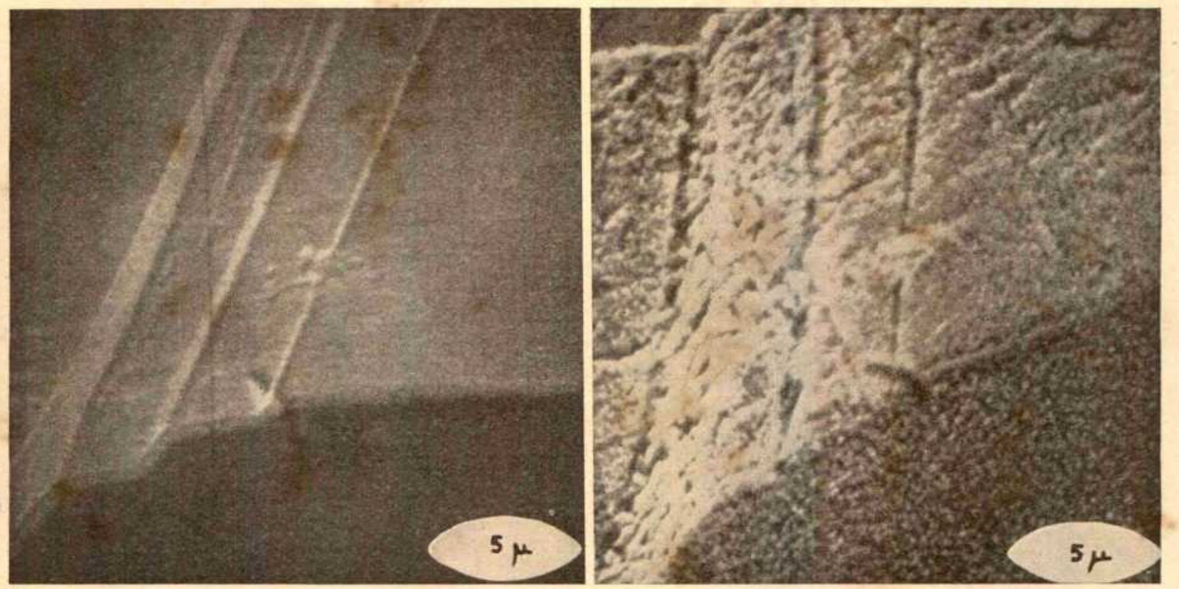

(a) (b)

Fig. 2. (a) Area of plate crystal of silver azide, before heating. (b) Same area after heating. Note the randomly oriented 'pebbles' of 0·2μ diameter

beam which scans the specimen rapidly, and the specimen is not heated or damaged by the examination. With the helpful collaboration of Mr. C. W. Oatley and Mr. C. K. A. Smith, we are using this instrument (in reflexion) to study the thermal decomposition of silver azide and other explosive crystals.

Experiment. The crystals of silver azide are allowed to separate from ammoniacal solution on to a silver plate. This plate is mounted on a heating stage in the microscope so that the temperature can be raised to about 400° C. It is necessary to silver the larger crystals to prevent charging; but with the small crystals it is unnecessary. Both needles and plates of silver azide were prepared in this way, the needles varying from 1 to 10μ in diameter thick and the dimensions of the plates from 10μ × 10μ × 0·5μ up to 300μ × 300μ × 5μ. It is necessary to keep the temperature of the specimen below the melting point of silver azide (250° C.) but higher than 120° C. to ensure an appreciable rate of decomposition. The progressive changes in the crystal as it decomposes can then be conveniently followed in the microscope.

Disintegration of the crystal. A stage in the decomposition of a small needle-shaped crystal about 1μ thick is illustrated in Fig. 1. The left-hand end of this crystal is in better thermal contact with the hot plate than the other and decomposition has begun here and spread part way along it. It will be seen that the crystal has disintegrated into small units about 0·3μ diameter which have taken the shape of rounded 'pebbles'. The volume of these 'pebbles' is estimated to be about one-half that of the original crystal. If the change to silver were complete it should be about one-third, so that the decomposition may not yet be complete.

The decomposition of a part of a larger flat crystal is illustrated: Fig. 2a is a region before decom-

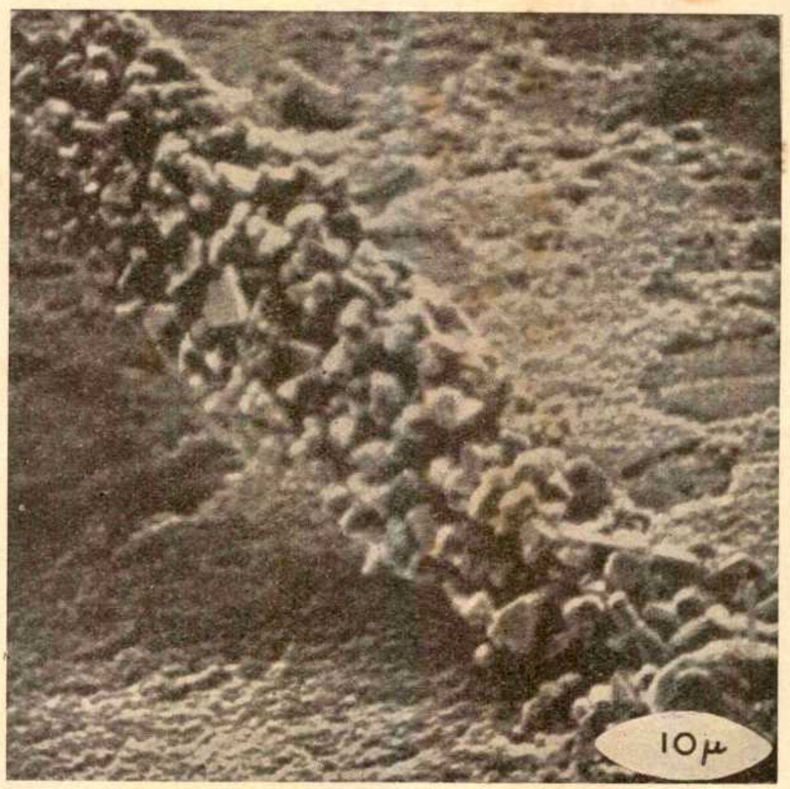

Fig. 3. Needle of silver azide which has broken up because of crystallographic phase change at 180° C. Note angular shape of fragments

position and (*b*) the same region after. Again it has decomposed into a number of 'pebbles' which are a fraction of a micron in diameter. The calculated volume of these is about one-third of the volume of the azide from which they are derived. This suggests that reaction is complete and the 'pebbles' are solid silver. It may be noted that the main body of the crystal has not contracted noticeably although it is being heated from the underside. It is a thin layer of the crystal adjacent to the surface which has decomposed first. This indicates that, in a large crystal, the volume adjacent to the free surface decomposes more easily, suggesting that free surfaces play an important part in the mechanism of decomposition.

The examination of a number of decomposing crystals show that this effect, the disintegration of the parent crystal into 'pebbles' about 1550–3000 A. in size, is general. The possibility that pebble size is determined by migration and aggregation of atomic silver (unrelated to the mechanism of disintegration of the parent crystal) cannot be excluded at this stage and further experiments at higher resolution are being made. The general behaviour, however, is consistent with the view that, in thermal decomposition, preferential reaction (with the formation of silver and the liberation of nitrogen) can occur on a fine network of dislocations which exist within the parent crystal. This would cause it to break up into units which continue to decompose until only silver remains. In any event, we may expect that the occurrence of reaction, and the liberation of silver and nitrogen within the crystal, will set up stresses which cause it to break along planes of weakness.

Polymorphic change. The decomposition of silver azide can be complicated by a crystallographic phase change which from X-ray studies is known to occur at about 180° C. (Sawkill, J., personal communication). If a crystal is heated to this temperature, the volume change accompanying the transition causes it to break up. Fig. 3 shows a crystal which has broken up in this way. The fragments are different in appearance from those of Figs. 1 and 2 in that they are angular in shape and generally hexagonal. Because of the poor thermal conductivity of the broken crystal, it was difficult to get further decomposition by heating, but some of these blocks finally decomposed to a product of size $0{\cdot}2\mu$ resembling the 'pebbles' in Figs. 1 and 2*b*.

These observations refer, of course, to the slow thermal decomposition of the azide; but parallel experiments on the fast burning and explosion of small crystals of various explosives are being made[6], using Courtney-Pratt's[7] high-speed ciné microscope camera. It is found that cracks develop in the crystal and run rapidly ahead of the advancing flame front, causing it to disintegrate into tiny flying undecomposed fragments which are burning on the surface.

It would seem therefore that, both in the slow and in the fast decomposition of these crystals, reaction does not occur only as a surface combustion. It can also occur within the crystal itself (probably as defects) and the parent crystal may break up into units which are only a few tenths of a micron in size. This break-up of the crystal will expose a large area of surface and will accelerate the reaction, so that account of it should be taken in any general study of the reaction kinetics of decomposing solids.

We thank Mr. Oatley and Mr. Smith for their active collaboration, I.C.I. (Nobel Division) for seconding one of us (J. McA.), and the Royal Society for a grant to the Laboratory.

FUNCTION OF CARBOTENOIDS IN CHLOROPHYLL-CONTAINING ORGANS

By Prof. L. CHOLNOKY, CATHERINE GYÖRGYFY, ELISABETH NAGY and MARTHA PÁNCZÉL

Institute of Chemistry, University of Pécs

WARBURG AND KRIPPAHL[1] showed that part of the energy necessary for the reduction of carbon dioxide in photosynthesis is derived from an enzymatic process in which a carotenoid participates beside nicotinamide and a heavy-metal ion. Recently Calvin, Stanier *et al.*[2] have suggested that carotenoids participate in photosynthesis; Calvin considers three possible alternative functions. It seems to us that our observations on carotenoids of the leaves, the unripe and ripe fruit of *Capsicum annuum* var. *lycopersiciforme rubrum* may be of some help in the elucidation of carotenoid function. Essentially similar results were obtained on *Solanum lycopersicum*, *Acer campestre*, *Aesculus hippocastanum*, *Spinacia oleracea*, etc.

The carotenoids were extracted with ether, saponified and divided between methanol and petrol-ether into epiphasic and hypophasic fractions by standard methods of carotenoid chemistry. The components of both fractions were separated by column chromatography. The concentrations of the resulting components were estimated with a Spekker photometer and identification was carried out by standard procedures (spectrum, mixed chromatogram, colour reaction with hydrochloric acid, analysis of furanoid derivatives, etc.).

The accompanying tables contain the results for leaves (Table 1), unripe (Table 2) and ripe (Table 3) fruits expressed in mgm./100 gm. fresh weight.

* Isolated in crystalline form.
† The accepted structural formula needs revision.

These observations indicate that the role of carotenoids in photosynthesis cannot be understood by considering a single carotenoid, but only by extending attention to all carotenoids and their relative changes during the life-cycle of the plant. Carotenoids serve oxygen transport and suffer transformation in consequence of this function. Primarily, carotenoids with β-ionon ring structure (β-carotene, zeaxanthin) are formed by the cells, and these are converted by the uptake of oxygen into the corresponding epoxydes (β-carotene-mono-epoxyde, antheraxanthin); after reduction they are either reconverted into the original compounds, or their α-isomers are formed (α-carotene, lutein).

Oxygen transport is conducted mainly by the system zeaxanthin → antheraxanthin → lutein, whereas the secondary system β-carotene → β-carotene-mono-epoxyde → α-carotene is only active when the primary system is unable to satisfy oxygen demand. In leaves containing chlorophyll, the transport of oxygen is operated at its maximum capacity and therefore the secondary system is also active. Consequently green leaves lack zeaxanthin, contain only traces of antheraxanthin and are rich in lutein. The participation of the secondary system is indicated by the presence of α-carotene, abundance of β-carotene and traces of β-carotene-mono-epoxyde.

In the unripe chlorophyll-containing fruit, the main system suffices for oxygen transport; therefore the secondary system is not functioning and consequently no α-carotene formed.

In the ripening fruit, after disappearance of chlorophyll, only zeaxanthin and cryptoxanthin take up oxygen and are transformed by it to epoxydes (violaxanthin, antheraxanthin, cryptoxanthin-mono-epoxyde). At this stage of ripening the epoxydes cease to deliver their oxygen and are transformed into polyenoxyketones (capsorubin, capsanthin, cryptocapsine). This explains the absence of lutein; at the same time, carotenoid synthesis exceeds the demand of oxygen transport and therefore zeaxanthin accumulates: the ripe fruit contains zeaxanthin but no lutein. The same process explains the absence of α-carotene in the ripe fruit: in the presence of abundant zeaxanthin, no oxygen is taken up by β-carotene and therefore no epoxyde and no α-carotene is formed.

Detailed results have been published[3] or are in the press[4]. The structure of the hitherto unknown pigments foliaxanthin, foliachrome, cryptocapsine and an isomer of cryptoxanthin will be submitted for publication in the near future.

The Virogenic Stroma in Nuclear and Cytoplasmic Polyhedroses

It has been found recently[1] that in the larval fat body and midgut cells of Lepidoptera and in the midgut cells of Hymenoptera infected with nuclear polyhedroses proteinaceous virogenic stromata form *de novo* in the nuclear sap. These stromata become increasingly proteinaceous and Feulgen-positive as they grow and develop. Morphologically they are networks, and virus rods differentiate within vesicles in their cords. These begin as fine rodlets about 60 A. × 1200 A. in size and increase *in situ* to their final size of 280 A. × 2800 A. They are then set free from their vesicles into the pores of the net by disruption of the surrounding cord material and may ultimately reach the ring zone between the centrally placed virogenic mass and the nuclear membrane. The freed virus rods become enveloped by independently formed and still-growing capsule membranes, within which capsule protein is deposited. The encapsulated rods then become occluded within crystalline protein polyhedra, which arise and grow in the ring zone and later in the enlarged pores of the late-stage infected nucleus.

However, little is known as yet of the development of the numerous cytoplasmic polyhedroses of lepidopterous larvæ. The polyhedra in these diseases form in the cytoplasm of the midgut epithelial cells, and spherical virus bodies about 60 mμ diameter are found occluded within them. Virus bodies have also been found present in the material between the polyhedra[2-4]; but the very first stages of infection, prior to the considerable formation of polyhedra by which these diseases are detected, are unknown. In particular, no virogenic stromata comparable to those found in the nuclear polyhedroses have been described.

In January, I found that many of the half-grown processionary moth larvæ (*Thaumatopoea pityocampa*) infesting the maritime pines in and around Athens (Greece) were infected with a naturally occurring cytoplasmic polyhedrosis of the epithelial cells of the midgut. In this disease virogenic stromata analogous to those formed in the nuclear polyhedroses have been found (Fig. 1). They arise subapically in the infected cells. Each virogenic stroma is a definite structural entity and in damaged cells survives as a discrete body when the cytoplasm has been destroyed. The stromata have a micro-net structure. In the cords of the stromata virus bodies arise, at first particularly in the more superficial parts of the masses. The virus bodies are spherical and consist of an extremely dense centre, about 35 mμ diameter, and a less electron-dense cortex, about 80 mμ diameter. The appearance of the virus bodies on grids after dissolution of the polyhedral protein suggests that their dense centres are composed of several elongated granules. When the virus bodies have been formed the cord material around them disrupts and liberates them into the larger pores formed as a result of dissolution of the cords. The virogenic stromata grow considerably (up to 10μ × 2μ) before small polyhedra, less than $\frac{1}{2}\mu$ in diameter, form, distributed irregularly over their surfaces. The freed virus bodies become occluded in the polyhedra. Numerous colonies (stroma plus associated polyhedra) penetrate as far as 50μ towards the base of each cell. As the masses grow, large pores form well inside them and polyhedra arise and grow there, occluding the freed virus. As the masses and their associated polyhedra continue to grow, the numerous colonies begin to fuse, finally forming one large colony per cell. The stromata finally regress and remain as small remnants within the large masses of polyhedra.

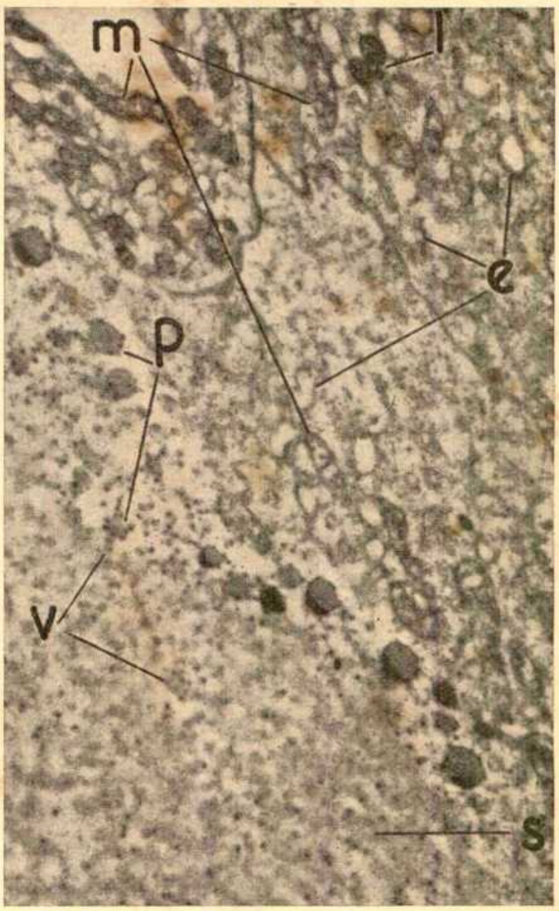

Fig 1. The section shows parts of two epithelial cells and one goblet cell (upper left-hand side). 'Normal' epithelial cell cytoplasm is present in the cell at the upper right-hand side. The cell at the left-hand side shows a moderately developed virogenic stroma. Its surface is sectioned obliquely in the upper part of the picture. *e*, endoplasmic reticulum; *m*, mitochondria; *l*, lipoid droplets; *s*, virogenic stroma; *v*, virus bodies; *p*, polyhedra. × 15,000. Electron micrograph taken by Miss S. Vernon-Smith

The cytoplasmic virogenic masses, unlike those of the nuclear polyhedroses, are protein and ribonucleic acid in composition and no deoxyribonucleic acid has ever been detected in them by Feulgen staining. The virogenic stromata possess neither mitochondria nor the endoplasmic reticulum of Porter[5] and Palade[6] and lack the ribonucleic acid small-granule component of Palade[7]. Where, however, fusion of the virogenic masses has occurred an odd mitochondrion or pigmented liposome is occasionally found surviving within the enlarged virogenic mass. As the stromata grow the endoplasmic reticulum, mitochondria and small-granule component immediately surrounding them disintegrate. Whether the disintegrated small granules are incorporated into the growing stromata is not yet clear. The stromata grow in the cytoplasmic matrix and may be considered as highly differentiated abnormal regions of the matrix initially induced by the viral materials absorbed by the healthy cell from the gut lumen. The virus bodies afterwards become differentiated from these stromata. The above observations indicated that, unlike the viruses of the nuclear polyhedroses which contain deoxyribonucleic acid only[8], those of the cytoplasmic polyhedroses would contain only ribonucleic acid. This was afterwards confirmed for the cytoplasmic polyhedrosis of *Sphinx populi*[9], in the polyhedra of which ribonucleic acid (0·9 per cent) was found but no deoxyribonucleic acid.

I am indebted to Dr. H. Hadjissarantos of the University of Athens for identifying the larvæ of *Thaumatopoea pityocampa*.

Preservation of *Strigomonas oncopelti* in the Dried State

In view of the findings of Becquerel[1] concerning the resistance of a wide variety of protozoa and algae to drying, it is rather surprising that more extensive efforts have not been made to preserve these cells in the dried state as is so commonly done with other micro-organisms.

Daily and McGuire[2] have published some data on the preservation of algae in the dried state; but there appears to have been no similar work done with protozoa.

This communication is an account of one of several similar trials in which the trypanosomid flagellate, *Strigomonas oncopelti*, has been preserved by a method of drying previously investigated for the preservation of bacteria[3] (see particularly appendix). The organism was kindly supplied by Dr. B. A. Newton, of the Department of Biochemistry, University of Cambridge.

The cells dried were obtained from a culture which had been grown for three days at 25° C. in 100 ml. of 2 per cent glucose broth. The copious growth was centrifuged and the packed cells were resuspended in an equal volume of 20 per cent glucose. Four-drop volumes of the suspension were inoculated on to starch–peptone plugs which were then exposed to high vacuum to produce foams. The necks of the ampoules were lightly plugged with cotton-wool to reduce contamination risks. After 24 hr. on the manifold, the dried foams were sealed *in vacuo*. Some of the desiccates were stored at room temperature (*c.* 20° C.) and others were stored at 4° C.

Three ampoules from each storage temperature were opened after twelve months (the longest period so far tested), and 3 ml. of glucose broth was added to each ampoule. The ampoules were left at room temperature. All ampoules yielded heavy growths of the flagellates, turbidity appearing in those which had been stored at 4° C. in about 9 days and in those which had been stored at room temperature, some 3 days later.

It is not possible from these results to gauge the efficiency with which the organisms were preserved; but it seems of interest to record that a relatively complex micro-organism such as *Strigomonas oncopelti* has been recovered after storage in the dried state.

I am indebted to the Medical Research Council for a personal research grant.

Isolation of a Heat-resistant Variant of Polio-virus

It has been shown[1] that when preparations of MEF_1 (type II) polio-virus (*P. hominis*) are exposed to heat at 50° C., there is a marked reduction in the rate of inactivation as the exposure time is increased (see Fig. 1). Bodian *et al.*[2] have suggested that such a phenomenon occurring during the inactivation of polio-virus with formaldehyde may be due to (1) protection of some virus particles by aggregation, or (2) the presence of inherently resistant particles, and concluded that there was no evidence to support the latter possibility. Since either of these possibilities may explain our results with heat as the inactivating agent, they formed the basis of further experiments.

The MEF_1 virus was a strain previously described[3], and all infectivity titrations were carried out in cultures of monkey kidney epithelial cells grown in the bovine amniotic fluid medium of Enders. Two methods were used for eliminating aggregates of virus particles, namely, filtration of infected tissue culture fluid through a Seitz *E.K.* pad or centrifugation at 10,000 rev./min. for 1 hr. The fluids so treated were exposed to heat at 50° C. and afterwards titrated as described by Stanley *et al.*[1].

Fig. 1 shows no significant differences between the inactivation curve of the control fluid and that of the fluid which had been filtered or ultracentrifuged. It therefore appeared that in this instance aggregation was of little importance.

Infected tissue culture fluid, cleared by centrifugation, was then heated at 50° C. for 40 min. and passaged undiluted. Degeneration of the tissue culture cells

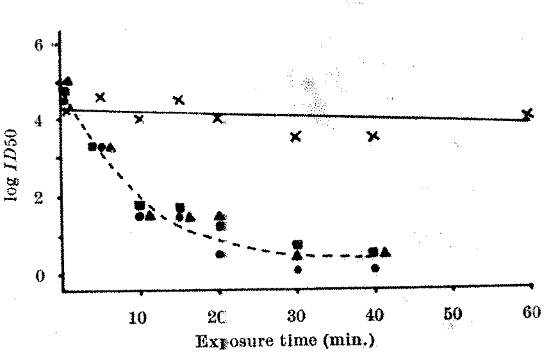

Fig. 1. Heat inactivation of *P. hominis* (50° C.). ×, Heat-resistant; ●, filtrate; ▲, infected tissue culture fluid cleared by centrifugation at 3,200 rev./min. for 20 min.; ■, ultracentrifuge supernatant

occurred after four days and the fluid was harvested, heated again for 40 min. at 50° C. and re-passaged. This process was repeated twice and a further heat inactivation curve obtained (see Fig. 1) using this material. It is apparent that the virus population comprising this passage differs markedly from the original preparation; and although it has now received four additional passages without further exposure to heat, there has been no reversion to the curve of the control material. Virus surviving exposure to heat at 50° C. for 24 hr. is now being examined.

It would thus appear that the inactivation curves originally obtained could be explained by the presence of a relatively small number of infective polio-virus particles inherently resistant to heat. This work will be reported in detail elsewhere.

Unidentified Chick Growth Factors in Fermentation By-products

'DISTILLERS dried solubles' are commonly used in the United States as animal feed ingredients, particularly in rations for young stock. They contain considerable amounts of most of the B vitamins; but in addition there is strong evidence of the presence of unknown growth factors[1]. It appears that part of the growth response which is shown when the product is added to practical rations complete in all known vitamins may be due to inorganic factors[2]; but it is evident that there is also some organic factor of biological significance[3].

Corresponding products are at present available only on a limited scale in the United Kingdom. The production of dried solubles recovered from malt whisky distilleries in Scotland has permitted investigation of the growth factors which they may contain. Field trials with chicks and turkey poults indicated[4] that when groups were fed rations balanced for known components, the rations containing dried solubles permitted more rapid growth (up to about 10 per cent) and better food conversion (about 3 per cent improvement). Accordingly, we determined to carry out more closely controlled investigations using purified diets and chicks from the same hatchery.

Some difficulty was experienced in formulating a purified diet which would support normal growth; but satisfactory results have been obtained from a ration containing casein, gelatin, maize starch, sucrose and lard. Fibre was provided by the addition of distillers dried grains, and the vitamin- and amino-acid-levels were maintained by the addition of synthetic products. The vitamin content was supplemented in this way to twice the level recommended by the U.S. National Research Council[5].

The dried solubles have shown a tendency to hygroscopicity and two methods are at present used for overcoming this. In the first method the dried solubles are mixed with distillers dried grains to provide a 40/60 solubles–grains mixture which is effectively free flowing. In the second method the syrup derived from the evaporation of the spent wash is specially treated before drying. Both these products (solubles–grains mixture and 'treated dried solubles') were used in the present experiment.

Six groups each of 25 White Leghorn × Rhode Island Red male chicks were used, two groups to each treatment, and the treatments were randomized in an electric tier brooder. The three rations were balanced to take account of the dried grains provided in the solubles–grains mixtures and the B vitamins in both the dried solubles products. All the rations contained procaine penicillin at 4 gm. per lb. Growth was normal in all the groups and the details were as follows:

Experimental arrangements

Group 1 Control ration
Group 2 Control + 7½ per cent solubles–grains mixture
Group 3 Control + 3 per cent treated dried solubles

Results

	Group 1		Group 2		Group 3	
	Weight (gm.)	Cumulative gain (gm.)	Weight (gm.)	Cumulative gain (gm.)	Weight (gm.)	Cumulative gain (gm.)
Initial	34·8	—	35·1	—	36·6	—
7 days	72·4	37·6	78·4	43·3	78·9	42·3
14 days	134·8	100·0	150·3	115·2	149·9	113·3
21 days	231·6	196·8	251·8	216·7	249·7	213·1
27 days	315·1	280·3	339·0	303·9	343·5	306·9
Food consumption per group	25,265 (gm.)		26,255 (gm.)		27,385 (gm.)	
Food conversion efficiency (gm. food/gm. weight increase)	1·88		1·84		1·82	

Statistical analysis of the four-week weights revealed that the standard error between treatments was 6·65 gm. and the response in groups 2 and 3 is shown to be highly significant at the 5 per cent level. There is no significant difference between groups 2 and 3, and it therefore appears that the treatment has not in any way affected the growth-promoting property of the solubles.

A more extended investigation is now under way and the design of the experiment has been modified to allow of more detailed statistical analysis. This work, which will include investigation of other potential sources of the growth factor, will be reported in detail elsewhere, together with the results of the field trials.

Chromatographic Separation of Digitalis Glycoside

SEVERAL of the constituents of *Digitalis purpurea* have been separated by paper partition chromatography, using ethylene glycol as the stationary phase and chloroform saturated with ethylene glycol as the mobile phase.

This system offers an advantage over the chloroform/formamide system used by Jensen[1] since the primary *A* and *B* glycosides as well as the secondary glycosides are separated before the solvent front reaches the bottom of the paper. Furthermore, any ethylene glycol left in the paper after drying will not react with the alkaline reagents, such as 3 : 5 dinitrobenzoate, commonly used to estimate the digitalis constituents, whereas formamide gives a marked reaction.

The toluene/propylene glycol system described by Zaffaroni[2] and used by Heftmann and Levant[3] for separating cardiac glycosides was tried but did not separate the digitalis constituents sufficiently for quantitative work.

In general, chloroform is preferable to toluene as the mobile phase for the separation of digitalis glycosides; propylene glycol and chloroform, however, are miscible and therefore unsuitable. On the other hand, ethylene glycol is relatively immiscible with chloroform and this combination has proved satisfactory. The method used is as follows.

Strips of Whatman No. 3 *MM* chromatograph paper 7·5 cm. × 55 cm. are passed through a 30 per cent v/v solution of ethylene glycol in methanol and blotted between folds of Whatman No. 1 paper. Solutions of the glycosides and aglycones in ethanol are applied to the starting line and the strips hung overnight in a chamber saturated with chloroform. Development is then commenced by allowing the mobile phase, chloroform saturated with ethylene glycol, to pass down the paper strips. There is a tendency for ethylene glycol to separate from the mobile phase in the trough and saturate the end of the paper, thus considerably slowing the rate of development. This may be prevented by placing a fold of dry Whatman No. 3 *MM* paper over this end of the strip before placing in the trough.

In the developed chromatograms each of the constituents occupies a small compact area with little tailing even when loads of 0·5 mgm. are chromatographed. Approximate R_F values are as follows:

Desacetyldigilanid *B*	0·05	Gitoxin	0·80
Desacetyldigilanid *A*	0·20	Digitoxigenin	0·90
Gitoxigenin	0·55	Digitoxin	0·95

Satisfactory quantitative recovery of several of the constituents has been obtained from the developed chromatograms, after removal of the ethylene glycol by heating for two days in a current of air at a temperature of 30° C. The glycosides present in alcoholic extracts of powdered digitalis leaves have also been separated and estimated.

The same solvent system has been used in preliminary experiments for separating mixtures of coumarin and related compounds, prior to testing for root growth inhibition. The degree of separation was of the same order as that obtained with systems containing butanol, acetic acid and water[4]. Chromatograms containing butanol and acetic acid in the mobile phase, after drying at room temperature for five hours, retained sufficient of the organic solvents to suppress completely root growth in cress seedlings. On the other hand, the amount of ethylene glycol remaining in chloroform/glycol chromatograms, similarly dried, did not cause significant inhibition of root growth.

Tumour-inhibiting Properties of Potassium Iodide Solution containing Potassium Iodate

F. B. OBERHAUSER *et al.*[1] have recently published results of experiments in which they tried to influence the growth of a rat sarcoma by oral treatment of the animals with solutions of potassium iodate in potassium iodide.

The surprising results obtained by these authors seemed to justify a repetition of the experiments using another strain of rats and a sarcoma obtained from another source.

We used male Wistar rats aged 3–3½ months and an average weight of 200 gm. These were implanted with 5–10 mm.^{3} samples of rats' Jensen sarcoma subcutaneously in the back. (We owe this tumour to Prof. Lettré from the Cancer Research Institute of the University of Heidelberg.) One hundred animals used in these preliminary experiments were divided into three equal groups. The animals of the first group were implanted with the tumour only, whereas those of the second group were treated only with the solution used by Oberhauser *et al.* by stomach tube. The animals of the third group were treated with 0·2 ml. of this solution three times daily for 20 days preceding the tumour implantation. Those of the fourth group received the same treatment 10 days before and 10 days after the tumour implantation. Finally, the fifth group were treated with 0·2 ml. of the solution for 20 days after the implantation.

The results can be summarized as follows. All animals of the first group, with the exception of two which died from a wound infection on the third and fourth day respectively, died within about 30 days. The majority of the animals in group 2 died from diffuse hæmorrhagic gastritis. In these, numerous erosions of the gastric mucous membrane were found and in some cases the stomach was filled with blood. Some animals died from bronchopneumonia. On the thirty-fifth day of the treatment only six survived; these too had lost much weight and were apathetic and without appetite. Most animals of group 3 died before the implantation of tumours, partly from hæmorrhagic gastritis and partly from bronchopneumonia, others from unknown reasons (some of the dead animals had been mutilated by their litter mates). Those animals which survived the pretreatment died from their tumours after an average of 30 days. The experiments of groups 4 and 5 had an analogous result.

The rats used in our experiments can therefore be said to have sustained great damage when treated with the solution described by Oberhauser *et al.* in the way and in the same quantity used by these authors, causing the death of the majority of the animals. Those animals which survived the treatment died from their sarcomas. No inhibition of tumour growth was observed with this treatment. The high mortality of the treated animals rendered it useless to continue these experiments on the basis of the dosage applied by Oberhauser *et al.*

Innervation of the Continuously Growing Incisor

To my knowledge, the development of the innervation of the teeth has not yet been systematically investigated. There have been sporadic remarks; for example, Holland[1] writes: "As far as nerve tissue is concerned, it is believed that there is no direct connection or hookup with the parent sensory nerve ganglion until the tooth erupts and until root formation is nearly completed". Different authors, for example, Powers[2], in her studies of tooth innervation, has given illustrations of the rat-pulp for myelinated fibres but only from the molar teeth and illustrations of the periodontal nerve supply from the continuously growing incisor of the same species. In several animals (dog, calf, pig) I have found that in the earlier stages of the tooth development, for example, the period before the root begins to grow, there are in the pulp only unmyelinated (presumably vegetative) fibres. Later the myelinated sensory fibres appear. The pulp of the continuously growing incisor of the rat shows a similar situation. There are only unmyelinated fibres differing in size and branching. These are mainly in the neighbourhood of the vessels (see Fig. 1) and do not reach the odontoblastic layer.

Assuming that this tooth—the most important in the rat—must have an abundant nerve supply, I studied the continuously growing incisor by several methods but with the same result. Here are occasionally fibres in the incisor which resemble in their size myelinated nerve fibres, as shown in Fig. 2; only by close observation they reveal themselves as consisting of two or more, sometimes twisted, fibres. Conceding the possibility of there being nevertheless myelinated fibres in the incisor pulp, they must be very rare. With the same technique as used by Romanes[3], many myelinated fibres (Fig. 2) regularly showed in the molar-pulps.

In my opinion, this phenomenon can be explained as follows. The continuously growing incisor of the rat (and perhaps other rodents) behaves as an ordinary developing tooth before root formation, so far as innervation is concerned. The fact that the labial side of this tooth is covered with enamel up to the basal end means virtually that this tooth consists only of a crown-tube. Both the developing ordinary tooth of the higher mammals and the continuously growing incisor are lacking in a sensory nerve supply. The difference is only that in the former case this is transitory and in the latter it is the permanent physiological status. Common for both is the fact that the tooth itself is in a developing state. The physiological foundation of this type of innervation is, in my opinion, as follows: the continuously growing incisor is wearing out by the physiological abrasion. The pulp-cavity or pulp-tube is by this abrasion slowly closed by irregular dentine production which is different from the so-called secondary dentine of the molars and resembles a degenerative calcification. The former often has an irregular structure with many holes in it. Despite this, a pathological process, for example, inflammation, very seldom occurs in the incisor of the rat. This fact may be connected with the above-mentioned absence or scarcity of the sensory nerve supply.

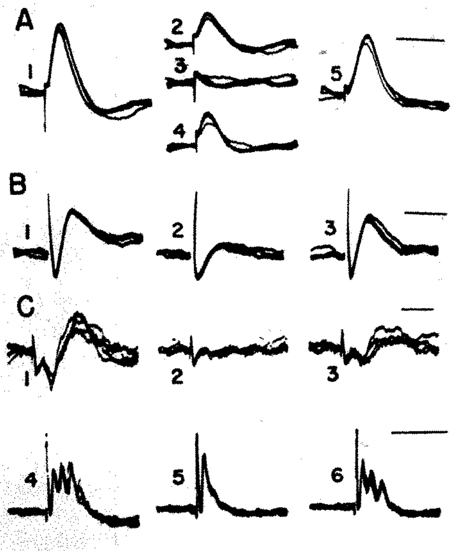
Inexcitability of Cortical Dendrites to Electric Stimuli

A PROMINENT component of the electrical activity of the cerebral cortex is the surface negative potential lasting about 15 m.sec. It is evoked synaptically by stimulation of various corticipetal pathways (for example, the callosal fibres or optic radiations), antidromically on stimulating the corticifugal pyramidal axons, or by stimuli directly applied to the cortex. This long-lasting surface negative potential has been ascribed, on good experimental grounds, to electrogenic activity in the apical dendrites of pyramidal cells[1].

Intravenous injection of *d*-tubocurarine (0·5–3 mgm./kgm. cat weight) into the succinylcholine-paralysed preparation diminishes and temporarily eliminates within 0·5–2 min. the dendritic potential previously evoked by any of the above modes of its production[2]. The disappearance and return of the antidromically evoked dendritic response evoked by stimulating the pyramids (C_{1-3}) parallels the disappearance and return of the late components of a volley descending in the tract after stimulating the cortex (C_{4-5}), which are of synaptic origin[3]. This and other evidence[2] indicates that in all modes of their activation the apical dendrites are excited by synaptic pathways, and therefore that their response is a post-synaptic potential[4]. However, when the dendritic activity to stimulation of the cortex (Fig. 1,*A*) or of structures 0·8–1·0 mm. below the cortical surface (*B*) is eliminated, the soma of the cells are still responsive to electrical stimulation. This is shown by the persistence of the first spike descending in the pyramidal tract (C_5), or of the surface positive spike to subsurface cortical stimulation (B_2). The cells then are also capable of antidromic invasion (C_2), as shown by the remaining positive spike of the records, whereas the apical dendrites are not accessible to invasion. These observations therefore lead to the conclusion that the apical dendrites are not themselves excited by applied electrical stimuli or by local circuit current. Similar evidence (unpublished) has been obtained for the dendrites of the cerebellar cortex.

Inexcitability to electrical stimuli is the condition prevalent in the electric organ of various fishes, and in the synaptically excitable membrane of the muscle end-plate and of the eel electroplaque[5]. In correlation with other observations, these findings have led to the suggestion[6] that the post-junctional membrane which is involved in synaptic action is always unresponsive to electrical stimuli. The present finding thus provides further experimental support for that suggestion, which has important consequences for the functioning of the central nervous system. The bearing of electrical inexcitability of the post-synaptic membrane on the nature of synaptic transmission, and on the classification and analysis of various forms of electrogenic activity, is discussed elsewhere[6].



Abolition of dendritic responses to electrical stimuli by *d*-tubocurarine chloride. Dose used in all experiments was 3 mgm./kgm. cat weight, intravenous.

(*A*) Stimulating and recording electrodes about 2 mm. apart on cortex. Four consecutive records superimposed in each set. Time, 20 msec. The normal surface negative response (1) was diminished 50 sec. after injection (2) and extinguished 20 sec. later (3). Recovery after 3 and 20 min. is shown in 4 and 5.

(*B*) Stimulating electrodes 0·8 mm. below cortical surface, recording electrodes on the latter. Three consecutive records superimposed in each set. Time, 20 m.sec. The positive spike, probably of cells, is followed by the negative dendritic potential (1). The latter disappeared 45 sec. after injection (2), with marked recovery 45 sec. later (3).

(*C*) Stimulating electrodes in pyramidal tract, recording on surface in 1–3. Electrode functions reversed in 4–6. Five consecutive superimposed records in each set. Times, 10 m.sec. The antidromically evoked cortical response is composed of two positive-spike components and a dendritic potential (1). Only the first spike component remained 2 min. after injection (2). Recovery after 20 min. in 3. The orthodromically evoked pyramidal response (4) was simplified, losing its synaptically excited components 2 min. after injection (5). Recovery after 20 min. in 6

Seasonal Variations of Noradrenaline and Adrenaline Concentrations in Rat Tissues

VARIATIONS of catecholamine concentration in tissues from normal male Wistar rats were observed in the course of experiments covering a twelve-month period; further estimations were afterwards carried out to confirm these variations. Adrenaline and noradrenaline were estimated fluorimetrically in heart, kidneys, liver, diaphragm, leg muscles, brain and spleen using a modification[1] of the method of Weil-Malherbe and Bone[2]. The results comprise between 24 and 74 individual estimations on each tissue extending over periods of up to 25 months.

Noradrenaline and adrenaline concentrations and the percentage of adrenaline in a mixture of these amines (the 'adrenaline percentage') usually showed two maxima and two minima in a year, often of very unequal size. Except for brain, their times and the approximate extent of variation in the first year are outlined below; the changes in liver are shown graphically in Fig. 1. *Noradrenaline.* $2\frac{1}{2}$- to $4\frac{1}{2}$-fold variation of the means obtained in different months; maximal concentrations in winter (November–January), with usually another maximum in summer (May–July). Minimal in spring (March–May) and late summer (August–September). *Adrenaline.* Two- to five-fold variations; maximal in July with a usually smaller maximum in winter (November–January); minimal in spring (March–May), and again in late summer (August–October). *Adrenaline percentage.* $1\frac{1}{2}$- to 3-fold variations; maximal in July and again in March; minimal in autumn–winter (October–January) and in early summer (April–June). The catecholamine concentrations already published[1,3] were obtained during the months September–November.

To obtain the most reliable estimates of significance, analyses from several consecutive months in both

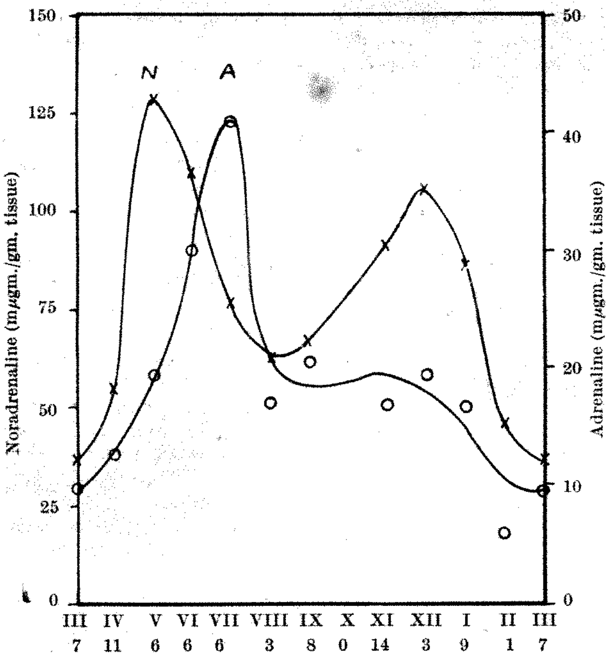

Fig. 1. Mean concentrations of noradrenaline (N) and adrenaline (A) in liver in different months, designated by Roman numerals. (Arabic numerals = numbers of estimations)

years were combined; there was at least one significant maximum and minimum ($P < 0\cdot01$) of noradrenaline concentration in each tissue and, except for spleen ($P < 0\cdot02$), of the 'adrenaline percentage'. There were significant or probably significant ($P < 0\cdot05$) variations of adrenaline concentration in each tissue. The variations of noradrenaline concentration in heart, liver, leg muscles and spleen, and of the 'adrenaline percentage' in heart, were significantly or probably significantly diphasic. Lack of significance in some cases was probably due to lack of estimates at times of probable maxima or minima.

There is little evidence of seasonal variation in brain; this might be due to a smaller number of estimates in this tissue although the estimates in spleen, of similar number, show significant changes. In brain the 'adrenaline percentage' varied notably less than in other tissues.

The means of estimates obtained in the second year were often considerably different from those of the first year; they not only confirmed but also exaggerated some of the changes originally observed. The seasonal changes are significant in spite of often larger standard errors incurred by combining estimates from several months and in two different years. The necessity of simultaneous control experiments is obvious; the changes of catecholamine concentrations outlined above are very much larger than those produced by, for example, insulin hypoglycæmia as determined by simultaneous analyses of untreated and treated rats[3,4].

Experiments with bilaterally demedullated rats indicate that the variations are not dependent on the adrenal medulla; they cannot be due to seasonal differences of environmental temperature or diet, nor solely to differences of light nor to interconversion of the two amines. They might have been caused in part by differences observed in the weight of tissues expressed as percentages of body-weight; seasonal metabolic changes, for example, of thyroid activity[5,6] or adrenocortical secretion[4], might without medullary secretion account for changes of weight and of the adrenaline and noradrenaline contents of tissues.

Recent experiments have shown that other catechol compounds which are extracted and estimated by the method are present to some extent in rat tissues; further experiments are required to determine the extent to which they contribute to the observed variations.

This work was supported by a grant from the Medical Research Council.

Measurement of Denaturation of Fish Protein

IT is well known that frozen fish alter in character during storage at sub-zero temperatures, becoming progressively tougher to eat, and exuding much fluid or 'drip' on thawing. The change proceeds more slowly the lower the temperature. There is a real need for an accurate objective method of measuring this deterioration, from the point of view of product control and also as a tool for systematic research on methods of freezing and storage. Most of the observed phenomena have been attributed to changes in the proteins of the flesh[1], and these changes have therefore been examined by a number of workers with the object of providing a successful method.

The proteins of cold-stored frozen fish become progressively less soluble in dilute salt solution. Dyer, French and Snow[2] showed that more than 90 per cent of the total proteins of fresh fish muscle could be brought into solution by suitable treatment, and worked out the optimum conditions for extraction. The percentage of soluble protein progressively decreased when the fish were cold-stored, and later experiments[3] showed a correlation between soluble protein and taste-panel rating (degree of toughness). However, further work[4] revealed that the scatter of values in individual fresh fish was too great for the measurement of considerable differences in denaturation. This fact reduced the value of the method, and has since led to its disuse in some laboratories, and to the investigation of other properties instead, for example, viscosity[5].

It seemed likely to us that if great variations were encountered in such a fundamental property as solubility, they would probably occur in others, too. We have therefore investigated these variations, having regard to the anatomy of the musculature and the biological factors affecting the living fish, in the hope that such information might point the way to a more reliable technique.

In the experiments to be described, flesh from cod (*Gadus callarias*) was chopped finely with scissors, macerated with 5 per cent sodium chloride at 0° C., and then centrifuged to separate soluble from insoluble proteins, which were determined as nitrogen.

The first finding of interest was a linear relationship between soluble protein and length of fish. In one experiment, for example, 92·2 per cent of the total flesh protein from a 10-in. fish was soluble in salt solution, while only 60·8 per cent was soluble in similar tissue from a 38-in. fish.

Fillets are made up of about fifty segments of muscle tissue proper (myotomes), each separated from adjacent ones by tough fibrous septa (myocommata). After some practice, it was found possible to dissect out the myocommata reasonably free from muscle tissue, and their solubility in salt solution was found to be very low—in one case as low as 20·8 per cent. It was obvious, therefore, that the presence of such tissue must depress the figure for extractable protein in whole chopped fillets, and since the myocommata were observed to be thicker in larger fish, it seemed likely that their presence was responsible for the length–solubility relationship noted above.

Tissue in different parts of a single fillet, with and without myocommata, was accordingly investigated. A fillet was divided into pieces each containing seven myotomes, and it was found that, in a 34-in. cod, the percentage of soluble protein diminished progressively from 75·6 at the anterior end to 67·8 at the tail. When the myotomes were dissected out free from myocommata, however, in the other fillet of the same fish, the corresponding values were 89·8 and 66·5 per cent, showing that the absence of myocommata resulted in a much higher solubility at the anterior end. There was no significant difference between dissected myotomes and whole tissue at the tail end because the myocommata there were too close together to be removed effectively. The important point was that even myotomes dissected free from myocommata differed in solubility in different parts of the fish. It was decided, therefore, as a routine to dissect out only two or three of the widest myotomes for investigation from each fish (near myotome No. 12 counting from the anterior end). When this was done, the soluble proteins of fish 16·5, 20 and 25 in. long were found to be respectively 97·4, 97·1 and 97·8 per cent of the total. In another experiment, values from fish 10, 24·5 and 38 in. long were 95·6, 96·1 and 91·9 per cent respectively. The lower values in very large cod were afterwards confirmed, but it can be seen that the relationship between solubility and body-length was mostly due to the presence of varying amounts of myocommata, and that the variations caused by differences in length were therefore almost completely eliminated by the dissection technique.

The effectiveness of this technique as applied to medium-sized cod was then investigated more fully, and when twenty-four samples of dissected myotomes from cod ranging from 20 to 31 in. long, caught in October 1955, were extracted with salt; they were found to yield on the average 95·7 per cent soluble protein, with a standard deviation of only 0·97 (extreme values 93·7–97·2). This was most satisfactory, but when the technique was applied to a similar batch of fish caught in January 1956, the average value had dropped to 87·5 per cent with standard deviation of 5·69 (extreme values 72·4–97·2), showing that a further influence was operative. Now cod in January are in a semi-starved condition, and the lower values compared with the October ones can probably be explained by the fish preferentially utilizing soluble protein for energy purposes or for building up gonads. The greater scatter of results, on the same hypothesis, can be attributed to the different degrees of starvation in different fish. By March, the average value had risen again to 93·1 per cent ± 3·69 (extreme values 82·3–96·2). We are continuing to investigate these points, as well as the possible effect of maturity. Although the low values for extractable protein in the largest cod are still unexplained, and, together with the seasonal variation, introduce difficulties in achieving a completely satisfactory method for comparing fresh and frozen fish, the new technique represents a very considerable advance.

It has already been applied in the following way. Fillets from seven medium-sized cod caught in the summer were frozen at widely differing cooling-rates, then stored at − 14° C. for about one hundred days. The soluble protein in the dissected myotomes was then determined, and showed that the amount of denaturation was considerably influenced by the rate of freezing. The pattern of results was strikingly reproduced in a similar batch of fish caught later, showing that differentiation between fish exhibiting small differences in denaturation was now possible.

A full account of the completed work will be published elsewhere.

Detection of a Presumptive Keto-steroid in the Ovaries and Blood of the Laying Hen

There is a considerable body of information on the occurrence of œstrogens and androgens in avian species. Much of the relevant literature has been reviewed by Sturkie[1], Lorenz[2] and Burrows[3]. In the absence of chemical or spectrophotometric evidence for the nature of the natural avian gonadal hormones, we have attempted to detect steroid œstrogens in extracts of the ovaries and blood of laying hens.

Ovaries were removed from laying hens immediately on killing and the large yellow ova were removed from their follicles and discarded. The residual ovaries were disintegrated in methanol in a Waring blendor with approximately twice their volume of methanol. The mixture was dialysed in 'Cellophane' dialysis tubing against methanol for 48 hr.[4]. The dialysate was diluted with water to 60 per cent (v/v) methanol and extracted with four successive portions of dichloromethane. The dichloromethane was removed at the suction pump. The residue was chromatographed on filter paper (Whatman No. 1) by the use of a ligroin–absolute methanol system at 34 ± 1° C.[5].

Examination of the paper revealed prominent spots which reacted positively to 2,4-dinitrophenylhydrazine, and which had an R_F value slightly less than that realized for pure œstrone under similar conditions. The spots were eluted from a number of papers with

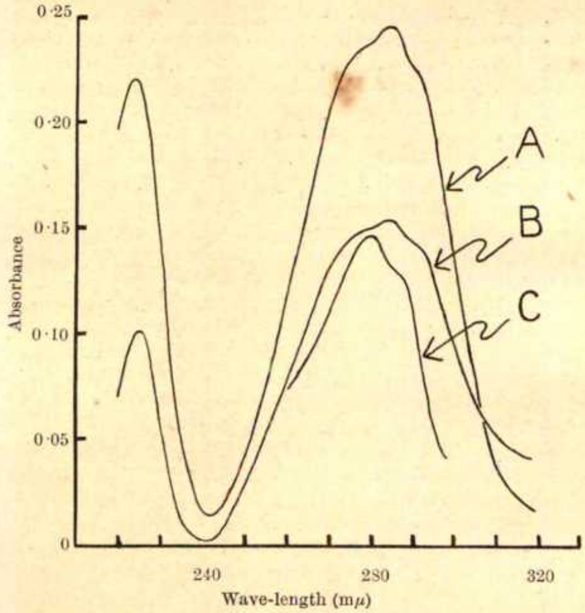

Fig. 1. Ultra-violet absorption of presumptive keto-steroids isolated chromatographically from ovaries (curve *A*) from blood (curve *B*) of laying pullets. Curve *C* was obtained from œstrone treated in the same way

dichloromethane–methanol (1 : 1 v/v). The eluted material was chromatographed repeatedly in the same system. The ultra-violet absorption spectrum of the eluate was recorded on a spectrometer (Warren 'Spectracord') after each run. After four such purifications the spot yielded material with the absorption spectrum shown in Fig. 1, curve *A*. The absorption peak at 283 mμ was close to, but distinct from, that obtained for pure œstrone (280 mμ) under the same conditions, and the absorption curve also indicated the presence of a 'shoulder' similar to, but different from, that shown by the steroid œstrogens (curve *C*). Finally, the Kober reaction was applied to the purified material according to the directions of Brown[6], the colour being observed in the Warren 'Spectracord'. The reaction was negative.

The same substance has been detected in the blood of laying hens. Whole blood was drawn into an equal volume of methanol, and a volume of water equal to that of the blood was then added. The mixture was dialysed against 60 per cent v/v methanol for 48 hr., and the dialysate was further examined as described above in connexion with ovarian extracts. A considerable number of papers, corresponding in all to about 2 l. of blood drawn from laying hens, was run. The areas on these papers that corresponded to the R_F values of the œstriol, œstradiol and œstrone were cut out, eluted with methanol–dichloromethane (1 : 1 v/v) and rechromatographed. A spot positive to 2,4-dinitrophenylhydrazone was found in the region corresponding to the R_F of the natural œstrogens. The ultra-violet absorption of this curve is shown (curve *B* in Fig. 1). It displayed close correspondence in detail with the curve for the substance obtained from the ovarian extract, and gave a negative result in the Kober reaction.

We are at present engaged in studies on the occurrence of this substance in relation to the reproductive cycle of the fowl.

We are indebted to the National Research Council of Canada for a grant in aid of research that made this work possible. One of us (R. H. C.) also wishes to thank the Royal Society for a Nuffield Foundation Commonwealth Bursary which enabled this project to be initiated during a visit to the National Institute for Research in Dairying, Reading, in 1954. We are further deeply indebted to Prof. W. A. Maw and Prof. N. Nikolaiczuk for providing suitable birds, and wish also to thank Prof. R. D. H. Heard of McGill University, and Dr. R. M. Fraps of the United States Department of Agriculture, for their interest and encouragement.

Extra Ocular Photoreceptors in the Land Leech, *Haemadipsa zeylanica agilis* (Moore) from Nainital, Almora (India)

THE special function of the segmental papillæ of the medicinal leech, *Hirudo medicinalis*, has long been in doubt. As far back as 1885, Whitman, in a study[1] describing the external morphology of the leech *Hirudo*, suggested serial homology of the segmental papillæ with the eyes. He supported this by the evidence that in sections of the segmental papillæ are found all the elements of the eye, except the pigment. Owing to the absence of a pigment cup holding the glassy cells, however, as is found in true visual organs, Whitman found it difficult definitely to regard the segmental papillæ as visual organs. The possibility that the segmental papillæ may be concerned with vision has also been suggested by me in my memoir on the Indian leech *Hirudinaria*[2].

A morphological study of the land leech *Haemadipsa zeylanica agilis* (Moore), obtained from the Nainital area, has revealed a closer structural resemblance between the segmental papillæ and the eyes than was hitherto described for other species. A section of the body-wall displays structures, each in the region of the segmental annuli, consisting of a single

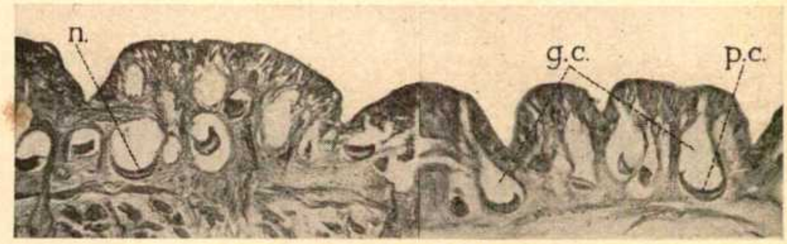

Fig. 1. Photomicrograp of a section through the body wall of the leech *Haemadipsa zeylanica*: *g.c.*, glassy cells; *n.*, nucleus; *p.c.*, pigment cup

glassy flask-shaped cell at the base of which is a layer of pigment with a nucleus embedded in it (Fig. 1).

The presence of the glassy cells together with the pigmented layer facing outwards is significant, and seems to point to a visual function for the papillæ, at least in so far as this species is concerned. It also supports Whitman's assertion that the eyes and the segmental papillæ were, originally, morphological as well as physiological equivalents.

Antigens and Mating Types in *Escherichia coli*

Evidence has been offered by one of us[1] for the existence of properties correlated with sex compatibility in *Escherichia coli*. According to these data, sex-incompatible ($F-$) strains have a lower acid agglutination point and a far greater stability of broth-cultures as compared with $F+$ strains of corresponding phenotype. These and other related properties of cell surface and the $F+$ state are transmitted infectively from $F+$ to $F-$ strains at the same time. A search for an antigenic equivalent of such properties was but an obvious implication of these findings.

Some strains of *Escherichia coli K* 12 employed in previous researches were used for preparing immune sera by inoculating rabbits intravenously. Two phenotypes were chosen, one of which is defined by biotin and methionine deficiency and resistance to the bacteriophage T_1, and the other by threonine, leucine and thiamine deficiency and inability to ferment lactose, maltose, galactose, arabinose, xylose and mannitol. The $F-$ and the $F+$ variants of each phenotype were used.

Both *O* and *K* antigens were prepared from each strain, aiming at providing evidence for the somatic or the capsular nature of the antigenic structure, if any, correlated with sex compatibility. The *O* antigen was prepared by heating young broth-cultures at 100° C. for 2½ hr. The thermolabile *K* antigen was prepared by suspending in saline smooth opaque colonies freshly grown on nutrient agar supplemented with 1 per cent glucose. Rabbits were injected at 4-day intervals and sera collected when test-bleedings revealed an agglutinating titre of about 1 : 1,000.

Fresh suspensions in saline of the four strains, that is, the two mating types of the two phenotypes, were used for the agglutination reactions. For this purpose cultures were used at the logarithmic growth stage under conditions which were optimal for both recombination and *F* infection.

The results of the agglutination reactions showed that: (1) anti-*O* sera give no appreciable agglutination with any strain unless the cells are boiled for 2½ hr.; (2) anti-*K* sera differentiate $F-$ from $F+$ untreated cells of the same phenotype in that they agglutinate $F-$ much more rapidly and in larger clumps than they do $F+$; (3) the phenotype and the *F* state of the antigen used for injecting rabbits do not affect appreciably the type of antibody produced, but the anti-*K* sera have a higher titre than the anti-*O* ones; (4) controls, either in the absence of immune sera or with normal serum from untreated rabbits, are fully negative; (5) the Kauffmann serum *O26 B6* (kindly supplied by Dr. A. Buogo) gives, with the same antigens, a reaction identical with that of our anti-*K* sera.

These observations seem to indicate that the antigenic difference, if any, between $F+$ and $F-$ cells of the same phenotype is to be understood as a difference in surface antigens, which is in good agreement with our previous results. Possibly, $F+$ cells are deprived of, or $F-$ cells are more abundantly provided with, a capsular antigen which seems to be of the thermolabile *B* type.

On the basis of these preliminary results, wider researches have been undertaken in order to: (*a*) analyse, qualitatively and quantitatively, the antigenic structure of *Escherichia coli* strains belonging to different mating types; (*b*) ascertain the effect of adsorbed antibodies on the kinetics of recombination and *F* infection.

Moreover, it is apparent that if *F* infection is substantiated, at least partially, by transformation of antigenic properties, these researches might also reinforce the interpretation of the well-known phenomenon of paragglutination[2].

5-Hydroxytryptamine in Scorpion Venom

In the course of an investigation of the toxic factors in the venom of *Leiurus quinquestriatus* (H. and E., 1829), one of the constituents of the venom has been found to be 5-hydroxytryptamine.

The venom was obtained by electrical stimulation of the telson[1], and was dried *in vacuo* and dissolved in water when required. The 5-hydroxytryptamine was identified by paper chromatography, developing with three different solvent systems and using the colour reactions with *p*-dimethylaminobenzaldehyde or diazotized *p*-nitroaniline, or the fluorescence produced after treatment with potassium dichromate and formalin (cf. Erspamer[2]).

Comparison of the areas of the spots with those from known concentrations of 5-hydroxytryptamine suggested concentrations of 3–4 μgm. 5-hydroxytryptamine base/mgm. dry venom. Assays of the crude venom on the rat uterus preparation or (with less precision) on guinea pig ileum confirmed these concentrations, and the activity of the venom on these preparations could be completely antagonized by dihydroergotamine. Assays of eluates of 5-hydroxytryptamine from chromatograms of the venom gave rather lower values, 1–2 μgm./mgm. venom; but eluates from other areas of the chromatogram did not show any activity on these preparations.

These concentrations of 5-hydroxytryptamine are even higher than those reported in wasp venom[3], and may contribute to the pain resulting from a sting. It is of interest that Mohammed and El Karemi[4] have claimed that a combination of dihydroergotamine and atropine, both capable of antagonizing

5-hydroxytryptamine, can protect mice from several lethal doses of venom. It seems unlikely, however, that 5-hydroxytryptamine, in these concentrations, can be a factor in the systemic toxicity of the venom, and extraction of the venom by 95 per cent (v/v) acetone, so that the 5-hydroxytryptamine is removed, does not appear to affect the toxicity of the residue.

Shell Disease in Portuguese Oysters

Since the discovery in 1949 [1] of shell disease among Brittany oysters relaid in Britain, detailed observations of its occurrence have been made. It is now established among native oysters, particularly in some of the warm shallow creeks in Essex[2]; but there is no previous record of its occurrence in *Gryphaea* as distinct from *Ostrea*.

In 1953, two naturally occurring Portuguese oysters, *Gryphaea angulata*, from the River Crouch were found to be lightly infected; but no further evidence that the disease attacked this species of oyster was obtained until September 1955 when Portuguese oysters from West Mersea, Essex, were found to be infected and in some cases to have died, as a result of the disease. 7·1 per cent showed evidence of attack compared with 9·0 per cent of the native *Ostrea edulis* on the same ground. 14 per cent of the infected Portuguese oysters and 22 per cent of the infected native oysters were in the last stages of the disease. The Portuguese oysters had been relaid from a variety of sources so that it was not possible to discover where the infection originated.

Symptoms are the same in both types of oyster: an initial appearance of opaque white clear-centred spots on the inside of the shell was followed by their coalescence and subsequent appearance of greenish-brown patches. When the area of the muscle is reached, there is interference with the closing mechanism, resulting in death.

Etiology of Atherosclerosis

A recent observation has been made which may have an important bearing on current views regarding the etiology of atherosclerosis. It has been observed that alimentary lipæmia, induced by a normal fat-containing meal (for example, a mixed grill), is inhibitory to the spontaneous *in vitro* fibrinolytic mechanism of blood which is active at *p*H 7·4 after dilution of the plasma[1]. The mean values in twenty normal subjects for the percentage of clot lysed in 24 hr. before, and 3½–4 hr. after, a fat-containing meal are as follow:

	Fasting	After fatty meal
Per cent lysis in 24 hr.	79 per cent	24 per cent

This observation may provide a bridge between the dietary[2] and mural thrombus incorporation[3] theories of the etiology of atherosclerosis. The sequence of events suggested is that a high food fat intake leads to a continuing inhibition of the fibrinolytic system of the blood and so to persistence of mural thrombi and their incorporation into the vessel wall.

Inhibition of *Venturia* spp. by Analogues of Host Metabolites

The significance of host metabolites in the host relations of *Venturia inaequalis* and *V. pirina*, the causal fungi of apple and pear scab respectively, has already been reported[1]. Further studies have shown that, of the main components of the mixtures of plant phenols in the apple and pear, compounds of the chlorogenic acid type, that is, depsides, probably play an important part. They are toxic to the pathogens at low concentrations, but do exhibit some phytotoxicity when injected *in vivo*.

In a search for a compound of this type, which would be more toxic to the pathogens than chlorogenic acid but less damaging to the host species, we have examined, first in culture, a series of structural analogues. The fungi were grown on filter-paper cylinders standing in filter-sterilized liquid media, and growth and sporulation were recorded[2]. Growth was visually assessed in categories, category 2 being arbitrarily assigned to a normal amount (not type) of growth. Sporulation was estimated by a turbidimetric method in which the readings were directly proportional to the numbers of conidia produced by the cultures.

An example of the reactions of *V. inaequalis* to the compounds studied is given in Table 1, the result of each treatment being expressed as the mean of six replicates. The basal culture medium contained

Table 1. Inhibition of Growth and Sporulation of *V. inaequalis*

Addition	Sporulation	Growth category	Notes
—	0·349	2	
Chlorogenic acid	0·187	2	Abnormal growth
Caffeic acid	0·178	2	Abnormal growth
Ferulic acid	0·332	2	
Protocatechuic acid	0·207	2	
p-Coumaric acid	0·220	2	
o-Coumaric acid	<0·001	1	Abnormal growth
Cinnamic acid	0·000	0	Inoculum ungerminated
Quinic acid	0·352	2	

glucose, an enzymic digest of casein, and inorganic salts; the final concentration of each added compound was $M/100$ and the initial pH was 5·6 in all cases.

Cinnamic acid was the most inhibitory compound and was unique in preventing germination of the inoculum. Introduction of a hydroxyl group in the *ortho* position, that is, *o*-coumaric acid, permits germination, but growth is abnormal and inhibited, and sporulation is strongly inhibited. Hydroxyl groups in any position in the benzene ring with the exception of a single hydroxyl group in the *para* position, that is, *p*-coumaric acid, cause abnormal growth, and even with the latter compound sporulation was slightly reduced. Ferulic acid, where the *meta* hydroxyl group is masked, also gives normal growth, while methylene dioxycinnamic acid, in another test, was more toxic than *o*-coumaric acid. Protocatechuic acid, which does not possess the —CH=CH.COOH grouping, permits normal growth but induces slight inhibition of sporulation. In contrast, it may be noted that protocatechuic acid is highly toxic to *Colletotrichum circinans*[3]. Quinic acid, a component of chlorogenic acid, had no effect either on growth or sporulation. Similar results have been obtained with *V. pirina in vitro*.

In view of the outstanding toxicity of cinnamic acid and its potential value as a protective fungicide and a chemotherapeutant, its activity in the latter role was studied *in vivo*. Shoots of Cox's Orange Pippin, raised under artificial light in a heated greenhouse, were inoculated with *V. inaequalis*, and, twenty-four hours later, all but the control shoots were injected with a 0·2 per cent solution of sodium cinnamate[1]. Only slight interveinal chlorosis and growth inhibition resulted despite an intake of about 100 mgm. per shoot tip. Thirteen days after inoculation a high degree of inhibition of *V. inaequalis* was observed in the sodium cinnamate treatment. A chromatographic examination of leaves above the injection point indicated the persistence of the cinnamate.

Further studies of this aspect of host–parasite relations, and of the chemotherapeutic value of compounds allied to host metabolites, are being continued and will be reported in full elsewhere.

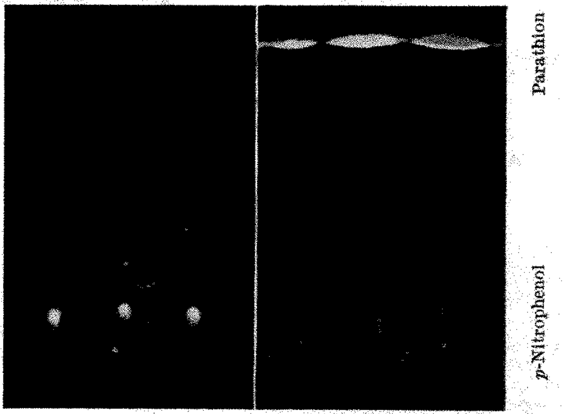
Isolation and Identification of Parathion in Biological Material

Numerous methods have hitherto been proposed for the isolation of parathion from biological material and for its identification. Most of these methods, have, however, defects which cannot be overlooked, resulting in either a small yield of poison (for example, steam distillation) or a highly impure extract (for example, isolation with the Stas–Otto method). Among the identification methods, the Averell and Norris[1] reaction has proved aspecific, while ultra-violet spectrophotometry and paper chromatography are highly disturbed by the impurities present in the extracts.



(a) (b)

Fig. 1. Chromatograms of parathion and p-nitrophenol using ultra-violet lamp of wave-length (a) 3600 A. and (b) 2537 A.

In trying to eliminate these inconveniences, I have devised a new system of isolation and identification which has given satisfactory results.

A preliminary extraction is made using the Fretwurst and Naeve[2] method: 10 gm. of the organ under examination are homogenized in a mortar with quartz, then diluted with 20 c.c. of distilled water, 20 c.c. of ethyl alcohol, and 50 c.c. of trichloroacetic acid at 20 per cent. After repeated shakings for 30 min. a portion of the mixture is centrifuged for 15 min. The supernatant liquid is filtered, the alcohol is evaporated and the aqueous acid solution is then filtered through a column of acid alumina prepared according to the method of Kuhn and Wieland[3]. No visible rings form; but parathion is completely adsorbed, while many impurities remain in the aqueous solution. The parathion is then eluted from the desiccated alumina with ethyl ether. The ether is filtered and evaporated with a weak air current. The residue is dissolved in benzene or alcohol and placed directly on the starting line of an *SS*2043*b* paper (28 cm. × 25 cm.) for chromatography. Simultaneously, test spots of parathion and p-nitrophenol are also placed on the paper. Development is carried out with the ascending method using as solvent 5 per cent ethyl ether in water-saturated petroleum ether. The paper is saturated in the vapour of the water phase of the solvent overnight. The run takes place in 2–3 hr. at a temperature of 20° C. The spots of the parathion and of its breakdown product, p-nitrophenol, are detected by two ultra-violet lamps, one at 3600 A. and the other at 2537 A. (Mineralight *SL* 2537), and photocopied according to Markham and Smith[4]. With the 3600-A. lamp the p-nitrophenol absorbs strongly, while the parathion absorbs weakly. Instead, with the 2537-A. lamp the parathion absorbs strongly: even 0·5 gamma of the substance is easily identifiable. The parathion has an R_F value of 0·98 and p-nitrophenol has one of 0·30. With this solvent we avoid the inconvenience of the partial transformation of the parathion in p-nitrophenol which is observed with alkaline solvents[5-7] or the necessity of working in 'reversed phase'[8].

A control to ensure the nature of the spots may be done by cutting strips from the chromatogram and examining them in ultra-violet with an adapter for the Beckman spectrophotometer model *DU*[9], first at wave-length 3200 A. (maximum for *p*-nitrophenol) and then at wave-length 2780 A. (maximum for parathion). With the first examination we obtain maximum absorption in the location of the parathion spot; the contrary occurs, on the other hand, when the examination is made with wave-length 2780 A. Sometimes the impurities still present in the extract alter the form of the spot, which becomes considerably flatter or wider: notwithstanding, the R_F value is not substantially modified, and, furthermore, the examination with the two ultra-violet ray lamps and an eventual successive transformation of the parathion into *p*-nitrophenol by ammonia vapour equally allow identification.

I am grateful to Dr. R. M. de Leo for his co-operation. Further details will be published elsewhere.

Ascorbic Acid Content in Fruits of *Myrciaria glomerata* Berg.

The fruit of the Brazilian plant *Myrciaria glomerata* Berg. has proved to be very rich in ascorbic acid. The ascorbic acid content was determined in the extract obtained by running the fruits (as a whole or in parts) in a blender for 2 min.; a 0·4 per cent oxalic acid solution was used for preventing oxidation during the extraction period and subsequent determination; ascorbic acid was assayed by the 2 : 6-dichlorophenol–indophenol method according to the technique described by Leme and Malavolta[1].

A marked difference in vitamin C content was observed in fruits from trees exposed to full sunlight when compared to those from shaded trees.

Tree No.	Mgm. ascorbic acid/100 gm. Full sunlight	Shaded
1	2,417	717·3
2	2,389	838·6
3	2,322	560·8

Assays made with fruits at different stages of maturity gave the following results:

State of maturity	Mgm. ascorbic acid/100 gm.
Green fruits	2,716
Fully developed fruits	2,391
Ripe fruits	2 417

Green fruits had thus a higher vitamin C content than either partially or completely ripe fruits; the difference between the last two types was not statistically significant.

Different parts of the fruit that were assayed separately had the following ascorbic acid content:

Part of the fruit	Mgm. ascorbic acid/100 gm.
Peel	2,482
Pulp (without seeds)	3,018

It is fortunate that the edible portion of the fruit, namely, the pulp, is richer than the peel.

The results herein reported show that the fruits of *Myrciaria glomerata* have the highest vitamin C content found among edible fruits of the family Myrtaceae; they are also among the fruits richest in this vitamin, being surpassed only by the hips of wild roses and by fruits of *Malpighia* spp.

Development of the Long Forms of Bacteria

Numerous methods of inducing long forms in aerobic and anaerobic bacteria have now been described[1,2]. One of the standard techniques of maintaining these forms is to grow the organisms beneath an agar block, that is, under microaerophilic conditions.

During the course of large numbers of experiments with shake cultures in quill tubes (3 mm. internal diameter), the medium being covered with various substances, the development of long forms has been readily observed. An account of this work is being prepared for publication.

Utilizing poor media (agar containing 2 per cent nutrient broth) it was observed that, with twenty different aerobic species (all catalase-positive) examined, a series of disks appeared below the meniscus at various depths up to 12 mm. (that is, to the depth of normal oxygen penetration). This phenomenon did not occur in this medium with catalase-negative organisms. When these disks are sectioned, long forms and typical *L*-bodies can always be seen (Figs. 1 and 2), sometimes for up to six weeks after incubation. The fact that sunlight increases the depths of the disks[3] suggested that the formation of hydrogen peroxide is the probable factor involved. If hydrogen peroxide is placed at the surface prior to incubation the disks appear at a very much lower level, whereas with catalase on top, growth occurs on the surface of the medium and no disks develop

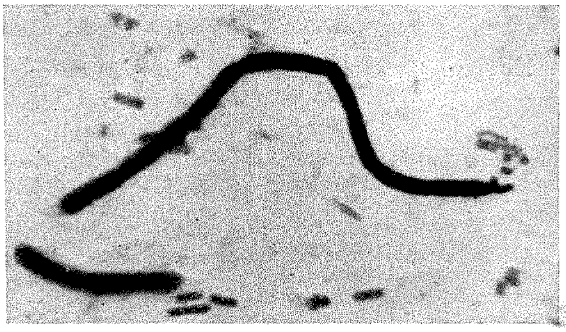

Fig. 1. *B. anthracis* showing normal and long forms (× 1,400)

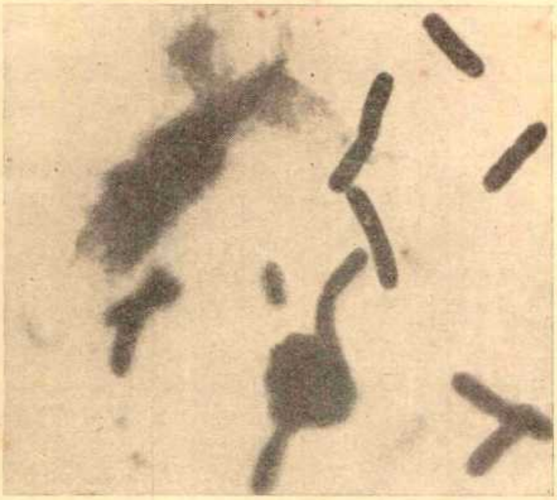

Fig. 2. *Cl. welchii* showing long forms and an *L*-body. (× 1,400)

(Fig. 3). The same effect is observed with aerobes in columns of nutrient agar topped with hydrogen peroxide (Fig. 4). Similar cultures (in poor media) incubated anaerobically for as long as a week do not develop disks until exposed to an atmosphere containing oxygen. This is strong evidence that the prime factor in the production of long forms is the presence of oxygen leading to hydrogen peroxide formation, and not necessarily a poor medium.

Hydrogen peroxide placed at the surface of shake cultures of anaerobes in nutrient agar produces increasing zones of inhibition according to the concentration of hydrogen peroxide used. The normal zone of inhibition is abolished if catalase is placed at the surface[4]. Again, at the surface of the column of growth of the anaerobes where the production of hydrogen peroxide is most active long forms can be readily observed.

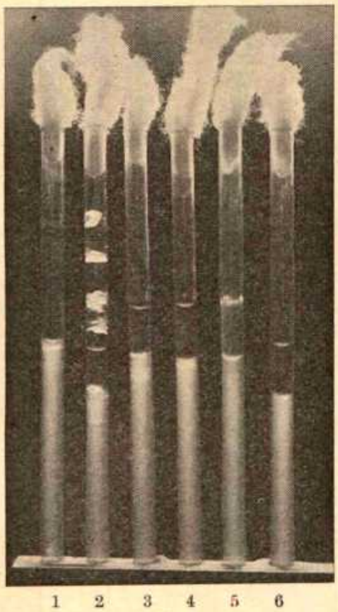

Fig. 3. The effect of hydrogen peroxide and catalase on the growth of *B. proteus* in poor media. Tube 1 exposed to air; tubes 2, 3 and 4 covered with hydrogen peroxide at 10^{-2}, 10^{-3} and 10^{-4} respectively; tube 5 covered with catalase; tube 6 negative control. (× ½)

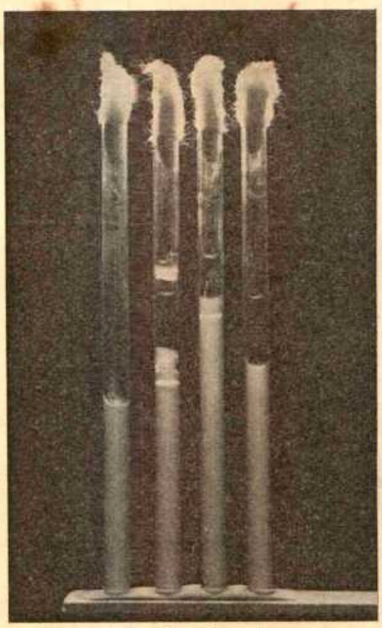

Fig. 4. The effect of hydrogen peroxide on shake cultures of *B. anthracis* in nutrient agar Tube 1 exposed to air; tubes 2 and 3 covered with hydrogen peroxide at 10^{-3} and 10^{-4} respectively; tube 4 negative control. (× ⅓)

It therefore seems altogether probable that these forms are produced by most bacteria when they are exposed to oxygen and either are deficient in catalase or are incapable of synthesizing this enzyme from the environment in which they find themselves. The fact that the strict anaerobes which are catalase-negative actively produce hydrogen peroxide[5] at the surface of the column of growth is also in keeping with this mode of *L*-formation.

It is more than likely that this formation of long forms occurs naturally when there is competition among organisms possessed of divers catalase content when growing on limited nutritive material in the presence of oxygen.

The fact that most viable organisms will either swell up or produce long forms in the presence of penicillin aerobically indicates that probably one of the main actions of this substance is to make the organisms more sensitive to hydrogen peroxide or to interfere with the synthesis of catalase from the medium.

It has also been observed that endospore formation of aerobic spore-formers occurs most readily just above the disks in these tubes in the presence of oxygen and this is again probably a direct effect of hydrogen peroxide on the cell. This is in keeping with the observations of Bayne-Jones and Petrilli[6] and Knaysi[7].

Effect of Temperature on the Spontaneous Activity from the Isolated Ganglia of the Slug, Cockroach and Crayfish

Most biological reactions respond to an increase in temperature by an increase of rate, and decrease their rate if the temperature is lowered. However, two preparations, that of the elasmobranch ampullæ of Lorenzini described by Sand[1] and by Hensel[2]; and that of mammalian peripheral nerve described by Bernhard and Granit[3], show an anomalous transient response to temperature.

In these, when the temperature is increased the preparations show a transient decrease in rate of spontaneous activity, whereas if the temperature is decreased, the activity shows a transient increase. The final rate of activity shows the normal temperature effect: it is faster at higher temperatures.

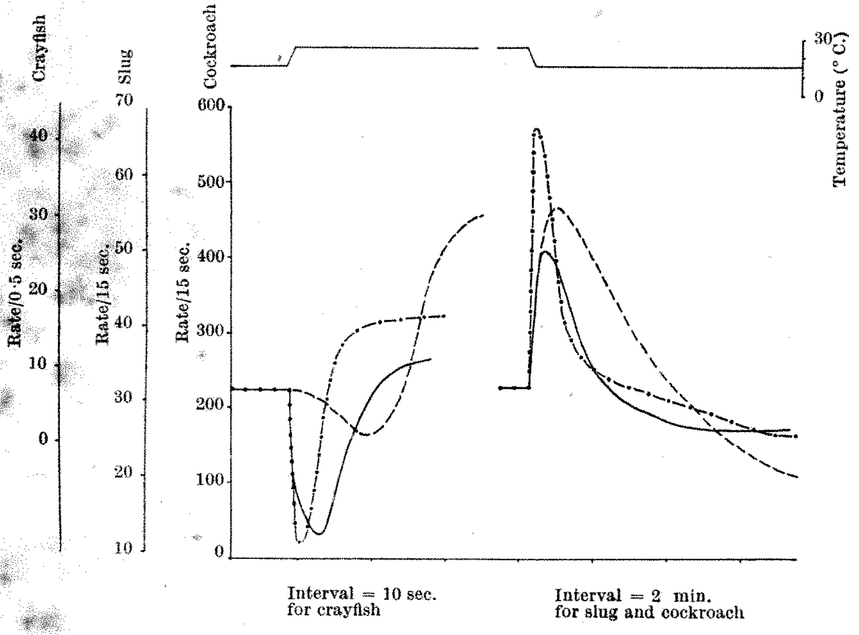

Fig. 1. Effect of change of temperature on the spontaneous electrical activity from the pedal ganglion of the slug ———, the abdominal ganglia of the cockroach —●—●—●, and the abdominal ganglia of the crayfish — — —

We have found three other preparations that show a similar anomalous transient response to temperature. These are the isolated pedal ganglion of the slug, the isolated thoracic and abdominal ganglia of the cockroach, and the isolated thoracic and abdominal ganglia of the crayfish. All three of these show spontaneous activity the rate of which is affected by temperature and temperature change. These effects are shown in Fig. 1. In all three an increase in temperature is followed by a transient decrease in spontaneous activity, whereas decreasing the temperature is followed by a transient increase in activity. This is true both for the rate of activity of single units and also for the number of units that become active. The effect is most clearly seen in the slug, where it takes approximately three to four minutes before the normal temperature effect is seen; it is most transient in the crayfish, where it lasts for about fifteen seconds after the temperature change.

Full details concerning the sensitivity of these preparations to temperature change will be published elsewhere.

Effect of Spore Coalescence on the Early Development of *Gracilaria verrucosa* (Hudson) Papenfuss.

Carpospores and tetraspores of *G. verrucosa* have been grown on microscope slides in running, natural sea water under constant illumination. After the initial attachment to the slide, divisions occur which correspond, in general, with the observations of Killian[1]. These produce, in 40–45 days, a dome of cells which may be 30–35μ high and 120μ in diameter. In the majority of isolated sporelings there is a great reduction in activity at this stage; but in some cases development of the shoot begins, in circumstances described below. The peripheral growth of closely adjacent spores leads to their meeting and coalescing into irregularly shaped 'rafts'. In these rafts individual sporelings cannot be recognized after a time unless their positions have been mapped at earlier stages. On all slides shoots have been first observed arising from rafts of this kind. Isolated sporelings, on the other hand, rarely show any change from the 40-day condition after several months, by which time coalesced sporelings of the same age have produced shoots several millimetres long. Shoots are not produced by all sporelings in a raft, and, when an extensive raft produces numerous shoots, these are well spaced out and seldom arise from adjacent sporelings. Furthermore, it will be seen from Fig. 1 that the larger rafts tend to bear proportionately longer shoots. On the slide concerned, the longest (1·8 mm.) occurred on a raft of about five sporelings. Larger rafts on the same slide bore more than one shoot, but none was longer. The largest raft, containing about fifty sporelings, bore ten shoots averaging 0·61 mm. in length, the longest measuring 1·6 mm. A ratio of five sporelings to each shoot seems usual in the larger rafts; but the frequency of the small shoots produced on isolated sporelings is much lower than 1 in 5.

Thus it seems that a shoot beginning development on a raft is able to obtain nutriment or growth stimulants not merely from its parent sporeling disk but also from the surrounding tissue. In fact, coalesced sporelings behave less as independent individuals than as a single organism. The observations suggest parallels with the organization of the apex of a higher plant, but this analogy obviously cannot be pressed far at present. Both carpospores and tetraspores show this behaviour. This is more surprising in the latter, which presumably include both male and female spores, than in groups of genetically identical carpospores.

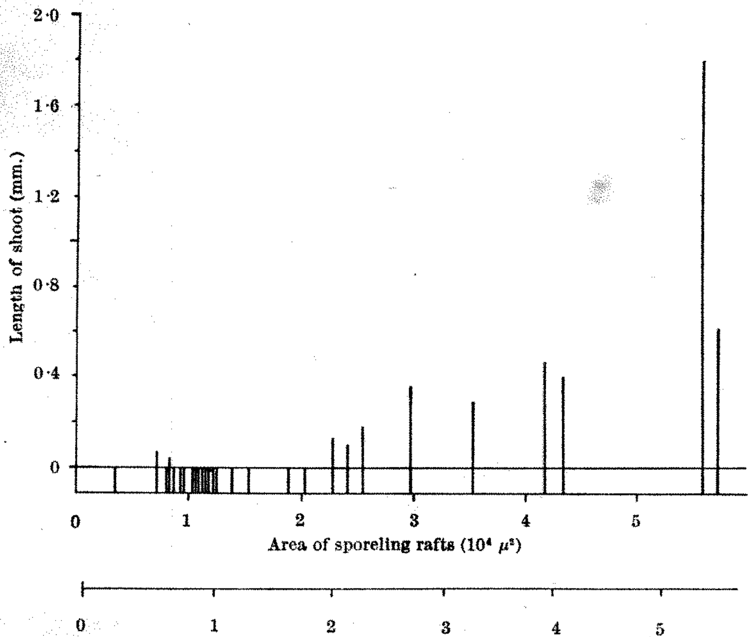

Fig. 1. Relationship between length of shoots of *Gracilaria verrucosa* and area of sporeling disks or coalesced rafts of disks bearing them after 80 days growth from carpospores. Lengths shown by lines above datum. Lines below this represent only the position of a single sporeling or raft. Areas of rafts are roughly proportional to the number of sporelings they contain. All sporelings or rafts bearing a single shoot or none are included. Larger areas bear proportionately longer shoots

Though it is possible that experimental conditions may be responsible, in part, for the results obtained, it is significant that sporeling rafts of the same kind, bearing mature fronds, have been observed on the shore. Speedier initiation and accelerated early growth of shoots would be of obvious ecological advantage to the plant. Its usual habitats are liable to frequent covering by sand; and the faster the early development of the shoot, the greater is the chance of its projecting above the sand surface, should the base become covered.

Rafts bearing several shoots appear very similar to Chemin's figures for *Grateloupia filicina*, *Lomentaria clavellosa* and *L. rosea*[2], and these may have arisen in the same way, though Chemin considered it more probable (in *L. clavellosa*, at least) that shoots developed from the expanded base of an original shoot. This is not the case in the present study.

Systematics of the Marine-Bug

Physiological barriers prevent most insect taxa adopting a marine life; but the bug *Aepophilus bonnairei* has surmounted some of these and lives abundantly at the lowest *Fucus* zone of rocky shores in south-west Britain. The better to understand the adaptive trends followed, a sound systematic basis is needed. The bug is placed in a monotypic family: but (1) in Gerroidea next to Mesoveliidae[1]; (2) adjacent to Cryptostemmidae[2]; (3) between the bedbugs and Anthocoridae[3], or (4) in Saldoidea but as a branch distinct from saldids and Leptopodidae[4]. Pruthi[5] showed the male genitalia of *Aepophilus* and some saldids to be almost identical and suggested that on this single character the marine-bug did not warrant separation from Saldidae; not a single writer has accepted this view, but it is now shown to be correct.

The female genitalia of *Aepophilus*, *Salda* and *Saldula* are not distinguishable *inter se*; they show a greater development of the third valvifer than is found elsewhere in Heteroptera; a second valvifer sclerotized as two distinct plates; identical first and second valvulæ and associated rami; secondarily incomplete separation of the first valvifers from tergum VIII. The egg guide is formed by separate first valvulæ above and a median membrane, marked by four longitudinal rows of little tubercles, below.

The head of *Aepophilus* has three pairs of dorsal trichobothria, a broad and large labium and a labrum with an almost non-existent first segment and lengthened third. The pretarsi are devoid of arolia or analogous structures: male and female genitalia, head, thoracic sclerites, tarsi and pretarsus and abdominal structure—there is a single dorsal abdominal gland in larvæ opening in front of tergum IV—all indicate that the marine-bug is a saldid, and confirmation comes from the male 'strigil'. In Saldidae this comprises a set of modified setæ on the third latero-tergite and a granulose plate on the second[6]; in *Aepophilus* there is an identical granulose plate, but the specialized setæ are lost. The acquisition of a general setal cover, loss of black pigmentation, reduction of fore-wings and loss of hind-wings are, together, evidence of such extreme modification that perhaps tribal status is deserved: such is now proposed as Aepophilini Puton *stat. nov.*, within Saldinæ.

It has been shown that some Saldidae (*Saldula* spp.) are adapted to survive regular tidal submergence on mud-flats[7]: many *Pentacora* spp. are estuarine, while two imperfectly known genera, *Orthophrys* on the Atlantic coat of Morocco and *Omania* on the Red Sea coast of Sinai, have been captured in rock crevices well below high water. In the last two there is loss of overlap of the fore-wings, reduction or loss of the hind-wings and reduction of the scutellum; but evidently *Aepophilus* has gone much the farthest along the way to complete adaptation to a submarine existence. The taxonomic distribution of the genera mentioned, and others, is such that we may conclude that many saldid genera are exhibiting parallel trends towards a partial or more nearly complete aquatic life.

An obvious specialization of *Aepophilus* is the presence of bubble-retaining areas on the pronotum, hemelytra and sternal region, but no plastron has been detected. The red coloration is paralleled by that of *Aepopsis robinii*, a carabid living in similar situations and often collected with *Aepophilus*[8]; this too has evolved from a group of predominantly black insects. In addition to the structural modifications, there are behavioural ones; for example, the bugs become immobile when suddenly submerged. Some simple experiments have demonstrated the value of the modifications: the marine-bug can survive at least 23½ hr. in still sea water, at least 49 hr. in running sea water; bugs kept in still sea water for 18 hr. were active immediately on release, those kept in boiled sea water for a similar period took about 30 min. to resume activity. Further work is in progress.

Transmission of Infra-red Light in Turbid and Clear Sugar Solutions

A well-filtered coloured sugar solution (in water) has an extinction-curve falling with increasing wave-length of light from near ultra-violet to red. Using as reference a clear, colourless sugar solution of the same concentration as the sample, it is possible to extend the observations in the range of near infrared without interference from the strong absorption bands of water at about 980 and 1,175 mμ. The extinction of the coloured sample will then show a continuous decrease with increasing wave-length up to a range of 1,000–1,100 mμ, where a flat minimum occurs. At still longer wave-lengths, the extinction rises again. The minimum extinction is very low compared with the optical density for visible light.

The same coloured solution, containing suspended particles (producing turbidity), shows the same behaviour, but naturally has a higher light attenuation than the filtered one at every wave-length. For solutions in the concentration-range common in sugar factories, the difference in optical density between unfiltered and clear-filtered solution is practically the same in the range 500–1,500 mμ.

Thus the presence of turbid matter can be indicated even in very dark solutions (for example, thick juices in sugar-beet factories and refinery liquors) simply by measurement of the transmission for light of about 1,050 mμ in a continuously flowing by-pass stream of the sample.

Unlike the procedure necessary for commonly accepted methods with the same purpose, the 'infrared method' does not involve any special preparation of the sample.

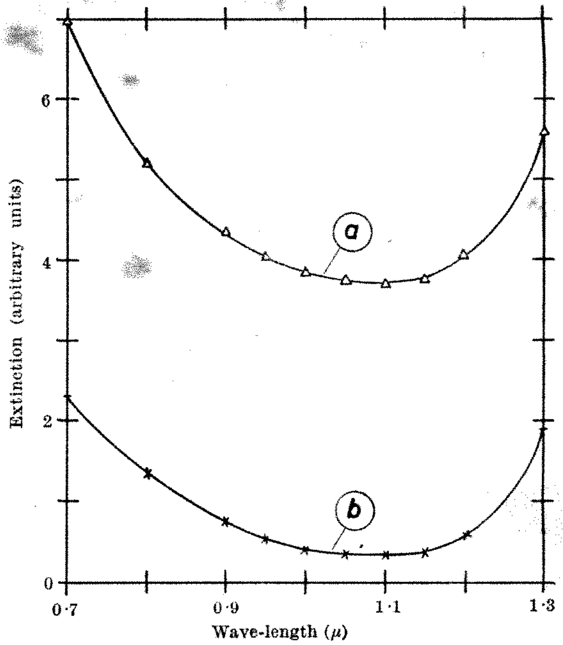

Fig. 1(*a*). Unfiltered sample of thick juice of sugar beet; (*b*) clear-filtered sample of the same juice

The phenomenon is exemplified in Fig. 1, showing a detail of typical extinction curves for one turbid and one clear-filtered sample of the same thick juice of sugar beet. The extinction value at 1,050 mμ for the filtered sample is in this case about 1/100 of the value at 463 mμ.

A full report will be published elsewhere. I wish to thank Mr. R. Lepik for valuable assistance in the investigation.

Setting of Gypsum Plaster

The initial thickening of slurries of hemi-hydrate type gypsum plasters has been considered by many workers to be due to a colloidal mechanism, whereas the further hardening and final setting have always been attributed to a crystallization process. Recent work supporting the colloidal theory is that of Fischer[1], while still later Becherer and Fiedler[2] have attributed the initial thickening of plaster slurries to the action of capillary forces causing a packing together of hemi-hydrate particles.

Work I have carried out on several commercial plasters has shown that crystalline dihydrate appears in measurable quantity before the initial set. It seems likely that the initial thickening of a plaster slurry is due to the formation of this small amount of dihydrate crystals, and therefore the complete setting process, both initial and final, is one of crystallization.

Samples of gauged plaster were removed from the mixing bowl at various times before the initial set, which was determined as described in the Standards Association of Australia Interim Specification No. 317[3]. These were washed with ethyl alcohol and then three times with water-free diethyl ether on a suction filter. After the last ether washing, the suction was continued for a few minutes to evaporate all ether, and the plaster was then in a dry powdered state. The washing with solvents took no longer than three minutes for each plaster sample. These samples were then examined by differential thermal analysis, automatic thermo-gravimetric analysis and X-ray analysis. Each of the three methods of analysis showed small amounts of dihydrate present in each plaster at the initial set. The presence of a dihydrate pattern in X-ray photographs at the initial set indicated that the dihydrate was in a crystalline form. A typical plaster which had an initial setting time of 33 min. showed no dihydrate present 13 min. after mixing, about 4 per cent dihydrate 25 min. after mixing, and 8 per cent dihydrate at the initial set.

It has been claimed by previous workers, for example, Neville[4], that hydration of hemi-hydrate does not occur before the initial set because of the very small rise of temperature during the initial setting period. Neville attributed this, in part, to the heat of wetting; but a gradual rise of 1 deg. C. which I have observed up to the initial setting stage represents about 8 per cent of the total temperature rise and I attribute it to the hydration of hemi-hydrate. The amount of hydration is consistent with the amount of gypsum observed at the initial set.

Where samples were taken prior to the initial set, amounts of dihydrate less than 2 per cent were detected by differential thermal and automatic thermo-gravimetric methods but not by the X-ray film technique. Percentages of dihydrate present in the gauged plasters were determined by the automatic thermo-gravimetric method.

A more detailed description of this work is to be published at a later date.

I wish to thank Mr. E. H. Waters and Dr. W. F. Cole (who also took the X-ray photographs) for helpful criticism during the work, which was undertaken as part of the programme of this Division.

Oriented Overgrowth of Paraffin Wax Crystals on Spherulites of Polyethylene

IN spite of the absence of polar groups in the paraffin molecule, oriented overgrowth of the crystals of paraffin wax can be readily obtained not only on ionic substrates such as sodium chloride and lithium chloride and on substrates with polar groups such as chloranil and anthraquinone but also on crystals of aromatic hydrocarbons; for example, anthracene and phenanthrene[1]. R. B. Richards[2] even obtained oriented overgrowth of paraffin wax crystals on the surface of strips of cold-drawn polyethylene.

We have found that the same overgrowth can be observed on spherulites of polyethylene. An example of the phenomenon is demonstrated in Fig. 1, which shows paraffin wax crystals grown in radiating array on the surface of a film of polyethylene crystallized by heating to about 170° and cooling slowly down to room temperature. The crystals of the paraffin wax (melting point 56°–58°) can be grown from a solution in petrol ether or benzene by evaporating the solvent.

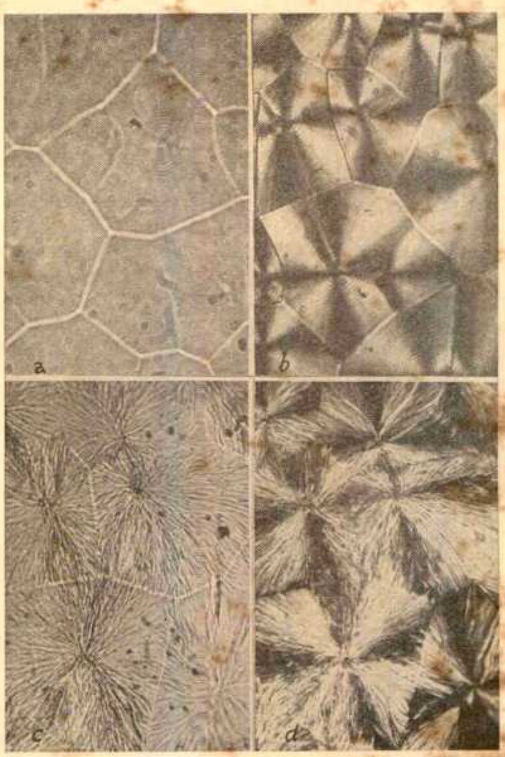

Fig. 1. Spherulites in a film of polyethylene. (*a*) Unpolarized light; (*b*) crossed nicols. Oriented overgrowth of paraffin wax crystals on spherulites. (*c*) Unpolarized light; (*d*) crossed nicols

The radiating array of the paraffin wax crystals on the spherulites of polyethylene is of special interest in view of a number of investigations of the structure of polymer spherulites (refs. 2–3 and others quoted in them) which led to the important conclusion that the molecules are tangentially orientated within the spherulites. This conclusion is largely based on birefringence evidence, and furthermore has been confirmed by X-ray diffraction. Bunn[5] has shown that the crystal structure of polyethylene is very closely similar to that of paraffin wax. Hence the paraffin wax/polyethylene system is, as Richards has pointed out, ideal for the occurrence of oriented overgrowth.

In strips of cold-drawn polyethylene on which oriented overgrowth was observed by Richards, sections of the polymer molecules in the crystalline regions are oriented approximately parallel to the direction of drawing. Paraffin wax crystals are flat plates with the paraffin molecules perpendicular or, in some cases, at an angle, to the plane of the plates. The oriented wax crystals appearing under the microscope as short needles are standing on edge with the plane of the crystals approximately perpendicular to the direction of drawing, that is, with the paraffin molecules parallel to the polyethylene molecules.

Thus in view of the position of the paraffin molecules in the paraffin wax crystals and the radiating array of these crystals on the spherulites of polyethylene, the overgrowth observed on these spherulites is in accordance with the conclusion that the molecules of polyethylene are tangentially arrayed in the spherulites.

Use of Pectin in Gel Electrophoresis

ELECTROPHORESIS of protein mixtures in agar gels has been described by Gordon *et al.*[1]. It has been developed by Grabar and Williams and used in their immuno-electrophoretic method[2]. The latter, thanks to the specificity and sensitivity of immunochemical reactions, permits the detection of the presence even of the smallest amounts of components in a protein mixture and permits defining them by their electrophoretic mobilities. The agar gels can be dried and stained[3], as in paper electrophoresis. However, the use of agar has one disadvantage: the samples are usually introduced in the gel, mixed with melted agar, thus being heated to 40°–45° C. Thus there is a constant danger of denaturing certain more sensitive protein components. A possible interaction of agar with some of the substances analysed cannot be excluded. Finally, it was of interest to find a gel from which the electrophoretically separated components could be extracted and estimated quantitatively.

Among a number of different substances yielding gels which have been examined by us, pectin seems to present certain advantages over agar. It can be gelled enzymatically at room temperature by pectinmethyl-esterase in the presence of Ca^{++}, the separation of proteins carried out electrophoretically, then either stained or cut out and the proteins released enzymatically by hydrolysis of the gel with pectinase. None of these steps affects the proteins. The latter can be estimated by one of the usual methods (biuret, protein nitrogen, etc.). The use of pectin furthermore has the advantage that the gel is prepared at room temperature and that the gelification can be more easily controlled. We found that the concentration of the pectin gel which gives very satisfactory results is 0·2–0·34 per cent, against that of 1·5–2 per cent of the agar. Thus electrophoresis takes place in 99·8 and 99·66 per cent buffer respectively, a condition approaching that of free electrophoresis.

Our method for preparing the gel is as follows. Immediately before use, to 15 ml. of a 2 per cent pectin-stock solution are added: 10 ml. of 0·65 *M* calcium chloride, 1 ml. 0·1 per cent commercial pectin esterase and 24 ml. double-distilled water, carefully mixed and finally diluted with an equal volume of veronal buffer *p*H 8·2 and ionic strength 0·60. The final ionic strength of the solution is 0·03. In recent runs we found that the mixture of borate and veronal buffers, as described by Consden and Powell[4], also gives very good separations.

The pectin–enzyme mixture is poured over a 13×18 cm. Eastman Kodak cover-glass, surrounded by a 0·5-cm. high wall made of heavy-duty aluminium foil. At both ends of the plates, filter paper strips (Whatman No. 1) are placed. The troughs in the middle of the plate, in which the serum samples are placed, are made in a manner similar to those of agar, except that we use as moulds small iron bars (approximately $10 \times 5 \times 2$ mm.), which after the gelation are removed by a small, but powerful, magnet. The empty trough fills in a short time with buffer and to this buffer 0·1 ml. of the sample to be analysed is added, thus yielding a final dilution 1 : 10 (the volume of the trough is about 1 ml.). The plate is then placed on an electrophoresis apparatus, the filter paper immersed in the buffer chambers in the usual way, and the current, 170–200 volts giving 18 m.amp., switched on. After 4–5 hr. the run is completed, filter paper strips removed, the gel is fixed by leaving it for 30 min. in a mixture of alcohol–acetic acid (250 ml. of 40 per cent v/v ethyl alcohol + 3 ml. glacial acetic acid) and finally stained in amidoschwarz for 6 hr. After this period, the excess of dye is washed out of the plate with 60 per cent alcohol–acetic acid mixture (250 ml. alcohol + 3 ml. glacial acetic acid) until the plate is well differentiated. A typical result of such a run with normal human serum is given in Fig. 1.

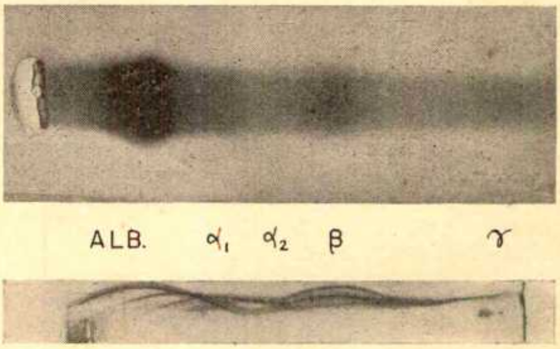

Fig. 1

Our present work consists of the quantitative estimation of these electrophoretically separated proteins, and the application of pectin gels to immuno-electrophoretic analysis (Fig. 1).

Coal Extracts as Promoters of Dropwise Condensation of Steam

When a very thin layer of a hydrophobic material is deposited upon a steam condenser tube, 'dropwise' rather than the more usual 'filmwise' condensation of the steam occurs ; and, owing to the elimination of the poorly conducting water film, the rate of heat transfer and therefore the rate of condensation is considerably increased. The capacity of a steam condenser of given size treated in this manner would be much greater than that of an uncoated condenser.

It has been found that when coals are extracted with certain organic solvents, an appreciable fraction of the coal substance is dissolved[1], and that the extract, after removal of the solvent, exhibits marked hydrophobic properties[2]. Promoters of dropwise condensation so far developed either have too limited a life in practice or contaminate the steam. It was thought possible that coal extracts might supply alternative materials for condenser-tube treatment which would prevent filmwise condensation over extended periods of use.

It is possible to obtain many kinds of extracts from different coals or carbonized coals by the use of a wide range of organic solvents. In the work described in this communication the results obtained with only two of the many that were tested are reported. These extracts were : (i) that obtained by the exhaustive Soxhlet extraction of a low-rank, free-burning coal with methyl-cyclohexanone (Sextone *B*), and (ii) that obtained by the exhaustive Soxhlet extraction of a shock-carbonized coking coal with chloroform.

The extracts were applied to $\frac{5}{8}$-in. outside diameter cupro-nickel condenser tubes as 1 per cent solutions in Sextone *B*. The method of application varied, either painting, dipping or electrophoretic deposition being used ; after applying the coatings, the tubes were drained and then baked at about 240° C. for 30 min.

These treated tubes were then placed in a single-tube test condenser condensing up to 200 lb. steam/hr./sq. ft. condensing surface and assessed by visual observation of the mode of condensation and also by measurements of the overall heat transfer. Fig. 1 shows an untreated tube on which the steam condensed as a film and Fig. 2 a treated tube upon which the steam condensed in the form of drops ; the overall heat transfer with the latter was 55 per cent higher than with the former (at a water velocity of 13 ft./sec.).

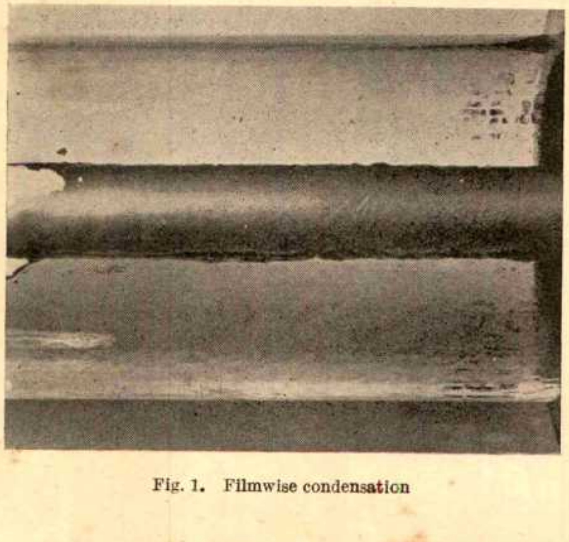

Fig. 1. Filmwise condensation

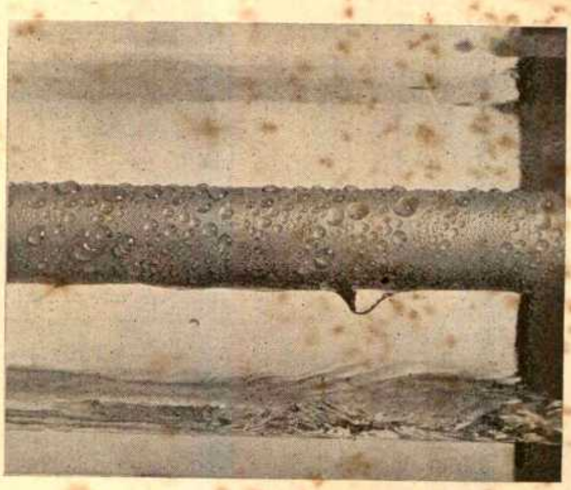

Fig. 2. Dropwise condensation

Tests have shown that the endurance of these promoters is markedly better than that of many other promoters that have been tried. Further tests are in progress.

Critical Temperature for Phase Separation of the Solid Solutions of Rare Gases

The rare gases argon and krypton form a solid solution at 77° K. that shows a positive deviation from Raoult's law[1]. At this temperature, the tendency toward phase separation may be estimated from the value of the energy of mixing parameter w_{AB}/kT of about 1·3. This value was estimated by the use of the crude treatment of regular solutions[2] on data taken in an apparatus not primarily designed for the task.

We have now made refined measurements in an accurately thermostated copper block fitted with a capsule-type platinum-resistance thermometer, and connected to a sensitive manometer. The measurements have been made on mixtures of krypton and xenon, because for this system the region of interest lies in the temperatures immediately above the boiling point of nitrogen. The total pressure at six temperatures was determined as a function of mole fraction, and the results at each temperature were fitted to the quasi-chemical theory of regular solutions[3]. The w_{AB} values so obtained were a linear function of temperature, and extended roughly to the critical value of the temperature, which was thereby estimated to be 90·2 ± 2·0° K.

For the krypton–xenon system, w_{AB}/kT has the value 1·3 according to the crude theory at about 113° K. If we assume that the mixtures obey a law of corresponding states, the data for the argon–krypton system indicate that the critical temperature of this solution would be 62° K.

A further analysis of these and other data will appear elsewhere.

Interferometric Spectroscopy in the Far Infra-red

Resolving power in the far infra-red region of the spectrum is limited in dispersion spectrometers by the small amounts of power available for measurement. The procedures for isolating unwanted orders with grating instruments and for discrimination against stray light not only reduce further the available power but also require elaborate instruments. We find an attractive alternative for this spectral region in interferometric spectroscopy, and this communication gives some pertinent experimental results.

Fig. 1 shows the response of a thermal detector to the resultant intensity from two interfering beams when the optical path-difference between them is changed. The reflexion interferometer used was 7·5 cm. in diameter and the maximum path-difference between beams was 7 mm. The spectral information contained in one half of Fig. 1 is displayed explicitly by its Fourier transform in Fig. 2. This transform was obtained by numerical analysis using a high-speed digital computer. The particular spectrum is of the radiation from a globar radiation source after reflexion from two cæsium bromide crystal surfaces and modified by the pure rotation absorption spectrum of water vapour. For comparison, a representation of the calculated rotation spectrum of the water molecule is given alongside.

The resolution shown here was arbitrarily restricted by the numerical analysis and does not represent the limit imposed by the maximum path-difference between beams. Since only reflecting elements are used in the optical system of the interferometer, the interferogram is symmetrical about the point of zero path-difference. This permits its representation by a Fourier integral containing only cosine terms.

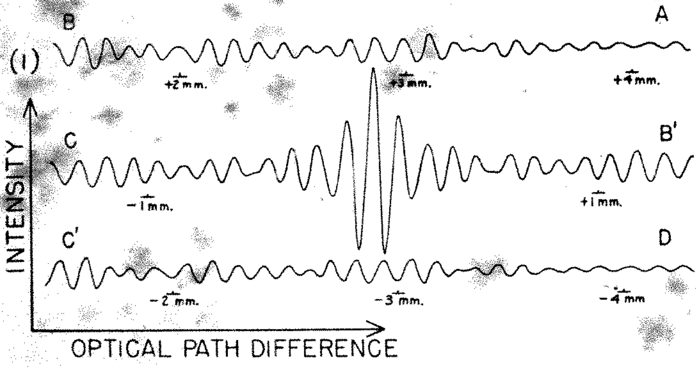

Fig. 1. Curve *ABB'CC'D*. Resultant intensity of two interfering beams as path-difference changes continuously

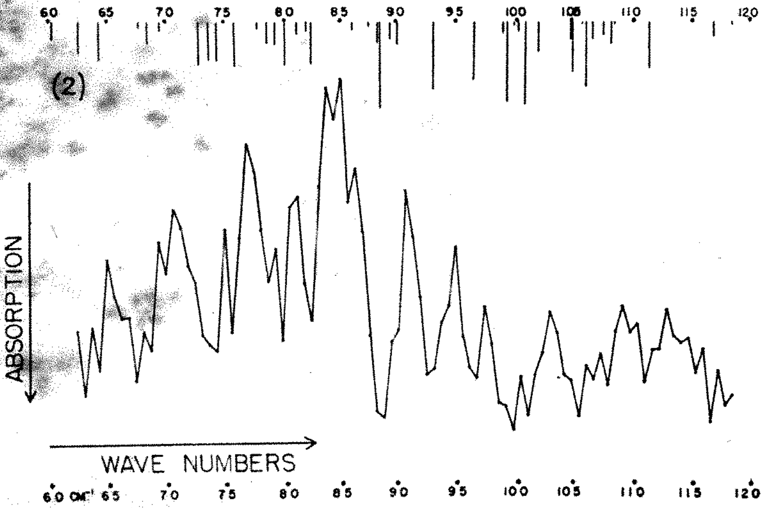

Fig. 2. Far infra-red reflexion spectrum of two cæsium bromide crystal faces modified by absorption spectrum of residual water vapour, with calculated water spectrum represented above

An additional significance of these results, for a region of the electromagnetic spectrum which has not been extensively studied, lies in the fact that the interferometer is readily adaptable to large construction to obtain greater light-grasp and resolving power.

A larger instrument with aperture 30 cm. has been made for study of atmospheric transmission in the submillimetre wave region.

We would like to thank various members, and Mr. G. M. Benson in particular, of the International Business Machines Corporation, Scientific Computation Laboratory, Endicott, New York, for their collaboration in applying digital methods to this problem. This investigation was sponsored by Air Force Contract AF18(600)-1307.

Semiconductors with Chalcopyrite Structure

It was recently reported[1] that certain compounds crystallizing with a triply substituted diamond lattice of the chalcopyrite type are semiconductors. We would report here optically determined energy gaps for a further four such compounds. These, together with the previously reported values for copper indium selenide and copper iron sulphide, are shown in Table 1.

Table 1

Material	Optical gap (eV.)	Material	Optical gap (eV.)
$CuInS_2$	1·2	$AgInTe_2$	0·96
$AgInSe_2$	1·18	$CuInTe_2$	0·95
$CuInSe_2$	0·92	$CuFeS_2$	0·53

The copper iron sulphide was of mineral origin; all other materials were synthesized directly from the constituents in sealed evacuated silica tubes. A more detailed account of the work is being given elsewhere[2].

Effects of Trace Elements on Embrittlement of Steels

In the course of investigations to assess the factors controlling the embrittlement of steels, a wide variety of steels of commercial origin has been studied. It was found that the Charpy impact transition ranges of all the steels were raised—although to varying extents—if the steels were exposed at 450° C. for lengthy periods. In many instances the transition range still remained below room temperature after exposure at 450° C., and the steels were not, therefore, brittle at room temperature. Nevertheless, it was apparent that an embrittlement mechanism was operating at 450° C. in all the steels.

It has long been suspected that trace elements play an important part in the embrittlement of steels, and steels of high purity have therefore recently been studied. Although the programmes planned are still far from complete, the results already obtained are of sufficient interest to justify reporting.

A commercial 3 per cent nickel–chromium steel of the *BS.En* 23 type, when oil-quenched as ⅝-in. diameter bar from 840° C. followed by tempering at 625° C. and water-quenching, had a Charpy *V*-notch impact transition range extending from −35° to 150° C. After reheating the hardened and tempered steel at 450° C. for 168 hr. and water quenching, the impact transition range extended from 230° to 20° C.

A steel of the same nominal composition, carbon 0·30 per cent, nickel 3·0 per cent and chromium 0·75 per cent, was prepared from carbonyl iron powder and other pure raw materials in powder form by compacting, sintering *in vacuo* and forging to ⅝-in. diameter bar. The Charpy *V*-notch impact transition range of this steel, after oil-quenching from 840° C. and tempering at 650° C. followed by water-quenching, was − 60° to − 200° C. This range was unaffected by exposure for 1,000 hr. at 450° C.

Another steel of the same nominal composition was prepared, using similar raw materials, by melting and casting *in vacuo*. The 22-lb. ingot produced was forged and rolled to ⅝-in. diameter bar. After oil-quenching from 840° C. and tempering at 650° C. and water-quenching, the impact transition range was again − 60° to − 200° C., and the range was unaffected by exposure for 1,000 hr. at 450° C. and water-quenching.

Now it is known that steels can be made, with impact properties which are unaffected by exposure at 450° C., it should be possible to assess the effects of each of the trace elements normally present in commercial materials by studying high-purity steels to which these trace elements have been added in controlled amounts.

Extension of Field of Application of Relaxation Methods of Computation

The availability of suitable computing machines makes it possible to consider the solution of sets of non-linear partial differential equations by the progressive reduction of residual errors over networks of points. The example below makes clear the process envisaged. I am not aware of any previous discussion of this process in such a general context.

The theory of turbulent gas jets[1] provides a simple example in which the field equations can be written as follows:

$$U\,\frac{\partial U}{\partial x} + V\,\frac{\partial U}{\partial r} + \frac{C^2x^2}{r}\,\frac{\partial}{\partial r}\left\{r\left(\frac{\partial U}{\partial r}\right)^2\right\} = 0 \qquad (1)$$

$$\frac{\partial U}{\partial x} + \frac{1}{r}\,\frac{\partial}{\partial r}\left\{rV\right\} = 0 \qquad (2)$$

In this case there are two dependent variables U, V; two independent variables x, r; and a constant C. The first step is to divide the region of interest into a network of points and take values of U and V at these points. The next step is to calculate the left-hand sides of the two equations at the points of the network and consider these residuals. Adjustments ΔU and ΔV must now be made to the initial values U_0 and V_0 to reduce the residuals to zero. To facilitate this work, $U_0 + \Delta U$ and $V_0 + \Delta V$ are substituted in the equations and only linear terms in ΔU, ΔV retained. Thus equations 1 and 2 become:

$$U_0\,\frac{\partial U_0}{\partial x} + V_0\,\frac{\partial U_0}{\partial r} + \frac{C^2x^2}{r}\,\frac{\partial}{\partial r}\left\{r\left(\frac{\partial U_0}{\partial r}\right)^2\right\} + \Delta V\,\frac{\partial U_0}{\partial r}$$
$$+ \Delta U\,\frac{\partial U_0}{\partial x} + U_0\,\frac{\partial \Delta U}{\partial x} + \left\{V_0 + \frac{2C^2x^2}{r}\,\frac{\partial}{\partial r}\left(r\,\frac{\partial U_0}{\partial r}\right)\right\}\frac{\partial \Delta U}{\partial r}$$
$$+ 2C^2x^2\,\frac{\partial U_0}{\partial r}\,\frac{\partial^2 \Delta U}{\partial r^2} = 0 \qquad (3)$$

$$\frac{\partial U_0}{\partial x} + \frac{1}{r}\frac{\partial}{\partial r}(rV_0) + \frac{\partial \Delta U}{\partial x} + \frac{1}{r}\frac{\partial}{\partial r}(r\Delta V) = 0 \qquad (4)$$

By treating U_0 and V_0 as known functions of x and r, the left-hand sides of equations (3) and (4) can be reduced to zero by familiar relaxation methods. At suitable stages in the work, where the residuals would be recalculated in linear problems, the adjustments ΔU and ΔV are incorporated into the values U_0 and V_0.

The prospect of finding solutions to any set of equations that arises is inviting. The arithmetic is likely to be formidable, but this is a matter of balancing the cost against the value of the result. The real difficulty is likely to be in selecting in each case a statement of the equations and a sequence of operations so that the procedure converges to the solution.

[1] "Modern Developments in Fluid Dynamics", edited by Goldstein, 595 (Oxf. Univ. Press, 1943).

MR. KNIGHT's letter inquires into the possibility of using computing machines to solve non-linear partial differential equations by the relaxation method. His suggestions imply two quite separate proposals: first, that non-linear equations can be solved by systematic relaxation; secondly, that the numerical processes involved can be programmed as a set of instructions to an electronic computer.

On the first question, reference can be made to accounts[1] already published of the application of relaxation methods to solve non-linear problems. To obtain the solutions described in those papers, it was essential that the relaxation method was employed in conjunction with very considerable human judgment, experience and imagination; these qualities cannot be taught to a computer. The systematic unimaginative relaxation process indicated by Mr. Knight could be performed by a computer; for several linear equations it would undoubtedly converge to the wanted solutions, though the time taken might be out of all proportion to the results achieved. But for non-linear equations there is no reason for hoping that the successive systematic relaxation of individual residuals to zero will converge, whether the calculations be performed by an electronic computer or otherwise. Indeed, it is almost certain that convergence could only occur as a fluke following a happy but accidental choice of the first guess to the values of the wanted quantities. The relaxational solution of non-linear equations demands, in my experience, human initiative.

It may, however, be of interest to record some recent experiments, which I have carried out in conjunction with Messrs. Ferranti, using one of their computers to solve linear partial differential equations by the relaxation method. In such work it is sufficient, but not practical, merely to programme the computer systematically to reduce residuals to zero point by point, for the time consumed in such a technique would be quite uneconomic. Indeed the computer must be capable of performing some of the devices which have previously been thought to be only in the capacity of the human operator. We have had most encouraging results in this investigation; the experiments are proceeding, and we hope to describe them elsewhere at a later date.

Determination of the Oxide Film Thickness on Tin

IN carrying out research in these laboratories on the corrosion of tin in anaerobic fruit acids, information was required on the thickness of the natural oxide film on tin. Since there appeared to be no published information about the thickness of tin oxide films, it was necessary to measure it; and for this purpose electrometric reduction has been found suitable. This method[1,2] is generally considered to be applicable only to metals more electronegative than hydrogen; but it succeeds for tin because of its high hydrogen overpotential. At room temperature the oxide film on tin probably consists of stannous oxide[3,4], and we have calculated our results on this basis.

The surface on which the oxide was measured was the flat end face of a cylinder 1 cm. diameter, made from Analytical Reagent tin. A mirror finish was obtained on this by polishing with emery papers, and finally with 'Silvo'. Any oxide film present was removed either by dipping in dilute hydrochloric acid, or electrolytic reduction. After washing with water and alcohol, the specimen was allowed to stand in dry air for the required period. The cylinder was then coated with cellulose lacquer, so as to leave only the polished end exposed, and placed in one limb of an *H*-cell apparatus, the other limb of which contained a platinum anode, and the electrolyte, 0·01 *N* potassium chloride. The two limbs of the apparatus, which was originally designed for polarization studies, were separated by a porosity 4 sintered-glass diaphragm. The apparatus was evacuated, and 'white spot' nitrogen admitted. Nitrogen was then bubbled for 2 hr. through the apparatus to de-oxygenate the electrolyte, and the apparatus again evacuated and nitrogen admitted. The electrolyte was forced by nitrogen pressure through the sintered disk into the limb containing the tin specimen. The oxide film was then reduced by cathodic polarization at a current density of 6 μamp./cm.^{2}, though a variation in this current density by a factor of four had little effect on the results. During the reduction, the potential of the tin was measured at frequent intervals against a silver–silver chloride electrode.

Typical potential-time curves are shown in Fig. 1. A well-defined plateau is obtained, corresponding to the reduction of the oxide film. The transition to the process of hydrogen evolution is sharp and the inflexion point at which the reduction is complete can be easily determined. Curve 1 was obtained after the tin had stood in air for 1 hr. The quantity of electricity required to reduce the stannous oxide formed in 1 hr. corresponds to a film thickness of 14–15 A., calculated on the apparent surface area, taking the density of the film as 6·3, the bulk density of stannous oxide. Curve 2 is typical of a surface that has been standing in air for 19 hr., and the oxide thickness after this period is 18–20 A.

Some tin surfaces were prepared by electropolishing in a solution of 100 ml. glacial acetic acid and 4 ml. 60 per cent perchloric acid at 0·2 amp./cm.^{2} for 2 min. Although a good bright polish was obtained, the surfaces were found to be covered with a film of unknown composition of the order of 1000 A. thick, which was not reduced at a constant potential, and which was not easily soluble in acids.

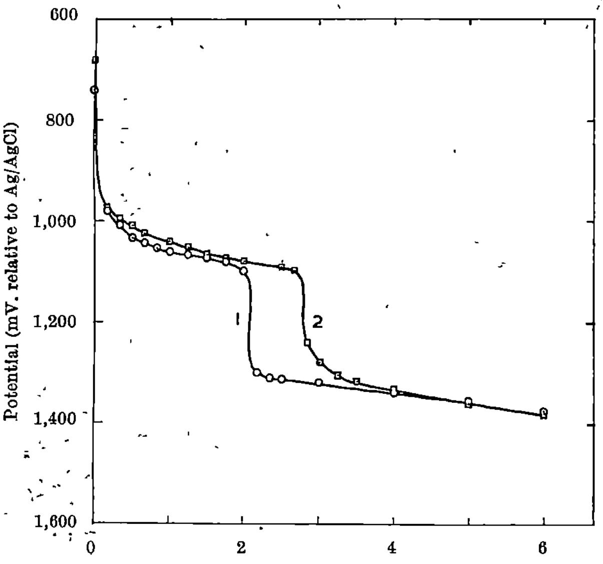

Fig. 1. Potential–time curves for the reduction of the oxide on tin (1), ○—○—, 1 hr exposure to air; oxide thickness, 15 A. (2), ⊡—⊡—, 19 hr. exposure to air; oxide thickness, 20 A

The method is also applicable to the determination of the oxide film thickness on tinplate.

Gravity Bases in Central Africa

IN the course of a two-month gravity survey of the Western Rift Valley of Africa, several stations of the Duclaux–Martin[1] African base network were re-occupied in order to calibrate the meter used. The results indicate a linear relation between the corrected readings of the present survey and the Duclaux–Martin gravity values to a high degree of precision.

Table 1

Station	Latitude*	Longitude*	Elevation*	Gravity (m.gal.)			Deviation (m.gal.)

* Co-ordinates and altitudes taken from references cited

During the months of December 1955 and January 1956, 392 gravity stations were occupied with Worden gravity meter *XP-O* in the Belgian Congo, Ruanda Urundi, Uganda and Tanganyika Territory in an attempt to delineate better the gravity anomaly associated with the Western Rift Valley. Among the stations reoccupied were thirteen Duclaux–Martin stations and nine stations occupied by Herrinck[2] for the Service de Météorologie et de Geophysique of the Belgian Congo. (Five of the above stations had been occupied by both the previous surveys; hence that is, seventeen separate stations are discussed here.) The Herrinck stations are part of a secondary base network of Congo airports using Duclaux–Martin values as a standard.

Meter readings were corrected using only two assumptions: (1) no reading error; (2) linear drift between control points. No special correction has been applied for the luni-solar tide. However, this effect, with a maximum deviation from the mean of about 0·15 milligal., was usually removed in the process of correcting for the drift. The corrected readings were then compared with the thirteen Duclaux–Martin gravity values, and a least square linear calibration equation was obtained. The resultant gravity values are given in Table 1 along with values obtained by Duclaux–Martin and Herrinck. Deviations are also listed. The standard deviation $m = \sum_{i=1}^{n} \Delta g_i^2/(n-1)^{1/2}$ between the Duclaux–Martin values and those calculated from the regression equation is $m = 0{\cdot}15$ milligal. with a maximum deviation of 0·29 milligal. at Kamanyola. Agreement with the Herrinck network, with the exception of the Irumu station, is also quite good.

The range of gravity values covered by the Duclaux–Martin reoccupations was 977,588–977,956 milligal. In this range of values there is an indication of non-linearity between the results of Duclaux–Martin and independent African survey by Harding[3] 1)). The results of this survey indicate that on-linearity is probably due to error in the ding values.

Further results from this survey will be published at a later date.

Effect of Rainstorms upon the Cotton Jassid in the Sudan Gezira

Empoasca lybica de Berg., a pest of cotton in the Sudan Gezira Scheme, invades the seedling crop early in September, the infestation normally reaching its maximum intensity in the last half of November. Hanna[1] records that peak populations of this insect are affected by rainstorms of 10 mm. and more in July and August as well as by dust storms in September. Field observations by Cowland and Hanna[2] suggest that populations upon cotton are also affected by rainstorms in September. Rainstorms, probably because of the mud which splashes on to the lower leaves, reduce the number of jassids infesting the cotton. Those findings which concerned the direct effect of rainstorms upon jassids at nine sites in the northern part of the Sudan Gezira were not reported by Hanna[1] in his published paper on rainfall and jassid numbers.

The late rains of September–October 1955 furnished three occasions on which to investigate the effects of rainstorms directly upon jassids infesting standing cotton.

A rainstorm of 10·6 mm. occurred during the afternoon of September 25, 1955, at the Gezira Research Farm. That morning, because of the hot humid weather associated with an approaching storm, counts of jassids in an observation plot (laid out for another purpose) had to be abandoned after two subplots had been examined. Next day, counts on remaining subplots were completed. The mean number of jassid nymphs per plant in the six subplots of the experiment are shown in Table 1.

On September 26 there were in all cases fewer jassids on the plants than on September 21, although from the incomplete count on September 25 the mean population per plant had increased during the previous four days. The figures from subplot II clearly show how the increase of population is followed by fall in numbers after the rainstorm on September 25.

Table 1. MEAN NUMBERS OF JASSIDS PER PLANT

Date of count	Subplot					
	I	II	III	IV	V	VI
21.9.55	0·37	0·18	0·29	0·16	0·26	0·16
25.9.55	0·61	0·43	These subplots abandoned			
26.9.55	—	0·14	0·18	0·03	0·17	0·12

Table 2. CHANGES OF JASSID POPULATIONS ASSOCIATED WITH A RAINSTORM IN THE NORTHERN GEZIRA

Zone	Replicates	Jassids/100 leaves			Rainfall (weekly periods)	
		Sept. 23	Sept. 30	Oct. 8	Sept. 23 to Sept. 30	Sept. 30 to Oct. 8
Within storm area	13	19·6	8·8	17·2	20 mm	Nil
Beyond storm area	12	9·9	23·4	36·5	Trace	Nil

Counts were made on October 2 and 4 of the number of jassid nymphs per 100 leaves at random in each subplot of a five-feddan field (about 5·2 acres). The field was divided longitudinally into three equal strips and each strip contained 20 subplots. During the afternoon of October 3, 9·3 mm. of rain fell upon this field at the Gezira Research Farm.

There were thus sixty pairs of 'before and after' rain counts of jassids in the same subplots. The mean decrease of population of 20·0 to 12·8 jassids per subplot was significant at 1 per cent level. There was, however, no significant difference between the twenty pairs of counts in the middle strip, although the pairs of counts in the subplots along the east and west edges of the field were significantly different at 1 and 0·1 per cent levels respectively.

A particularly striking example of the check of jassid numbers associated with a rainstorm in a roughly triangular area of about 300 square miles in the northern Gezira occurred on September 26, 1955. Within that area rain-gauges registered between 16 and 29 mm. of rain; outside the area gauges showed a 'trace' to 5 mm.; this was the last storm of the season in that area. Table 2 shows the relevant jassid count per 100 leaves.

Between the 'before and after' rain counts inside the storm area, the observed mean fall of population is significant at 1 per cent level, while beyond the storm zone the increase of population in the same period, September 23–30, is significant at the 1 per cent level. Inside the storm area, all counts on September 30 were less than the corresponding count on September 23; but outside the storm zone the exact reverse was true.

A map showing the locality of the sampling areas and rain gauges has been deposited at the British Museum (Natural History), South Kensington.

While the checks to breeding associated with rainstorms tend to delay the build-up of jassid population on cotton, observation at the end of November, the time of peak populations, showed no marked differences in the number of insects on the cotton within and beyond the storm area of September 26.

We wish to thank the Chief of the Research Division and the General Manager of the Sudan Gezira Board for permission to publish this communication.

At 11 a.m.—(in Sheffield Cathedral).—Religious Service. Preacher: the Rt. Rev. the Lord Bishop of Sheffield.

Monday, September 3

At 10 a.m.—Dr. T. Robertson: "The Presentation of Geological Information in Maps" (Presidential Address, Section C).

At 10 a.m.—Prof. D. Whitteridge, F.R.S.: "The Machinery of Posture" (Presidential Address, Section I).

At 8 p.m.—Prof. Sydney Chapman, F.R.S.: "The International Geophysical Year".

Tuesday, September 4

At 7.30 p.m.—Sir John Cockcroft, F.R.S.: "The Future Development of Atomic Energy".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Student in the Department of Botany—The Registrar, The University, Hull (September 1).

Glaciologist (with an appropriate university degree) in the Antarctic Division of the Department of External Affairs, Canberra, for duties with the 1957 expedition to Mawson, Australian Antarctic Territory—The Senior External Affairs Representative, Australia House, Strand, London, W.C.2 (September 8).

Physicist, Basic grade (with or without experience), for work on X-rays, gamma-rays, radioisotopes and some electronics—The Administrator and Secretary, University College Hospital, Gower Street, London, W.C.1 (September 8).

Assistant Experimental Officer (with a pass degree or at least general certificate of education (advanced level), and preferably experience or training in horticulture) in the Irrigation Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (September 10).

Assistant Lecturer (Organic Chemistry)—Dr. L. N. Owen, Chemistry Department, Imperial College of Science and Technology, London, S.W.7 (September 10).

Physicist or Physical Chemist (with good honours degree and wide research experience, and preferably experience in modern analytical techniques, particularly infra-red spectroscopy and gas/liquid chromatography), for fundamental work connected with the kinetics of carbonization of coal—The National Coal Board, Coal Research Establishment, Stoke Orchard, near Cheltenham, Gloucestershire, quoting SS/370 (September 10).

First Assistant (Senior Lecturer grade) (medically qualified with experience in physiological research) in the Research Department of Anæsthetics—The Secretary, Faculty of Anæsthetists, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2 (September 12).

Agricultural Economist (with a degree in agriculture or economics together with experience in the field of agricultural economics, preferably on farm management inquiries or production cost investigations) in the Federal Ministry of Agriculture, Federation of Rhodesia and Nyasaland—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (September 15).

Physicist (with a first- or second-class honours degree in physics, an interest in electronics and a liking for experimental work, and also willing to develop interests in classical and biological physics) with the Air Ministry at Farnborough, Hants, for research on problems connected with applications of physics to aviation medicine—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.190/6A (September 15).

Senior Lecturer in Agricultural Chemistry—The Secretary of University Court, The University, Glasgow (September 15).

Research Assistants (2): one in inorganic chemistry and one physico-organic chemistry—The Secretary, The University, Exeter (September 17).

Chair of Mechanical Engineering at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia September 29).

Engineer (with an honours degree or equivalent in physics or electrical engineering and experience in the design and construction of electronic apparatus) in charge of Nuclear Equipment in the Department of Physics—Dr F. B. Kipping, University Chemical Laboratory, Lensfield Road, Cambridge (October 1).

Senior and Junior Research Fellows (with a first- or second-class honours degree in an appropriate subject and able to show evidence of a very high standard of ability in research) at Government Scientific Establishments for research into subjects of importance to H.M. Government—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4567/56 (October 31).

Director of the Western Australian Museum—The Hon Mr. Justice Wolff, President, Museum and Art Gallery of Western Australia, c/o The Supreme Court, Perth, Western Australia (November 30).

Agronomist; Plant Breeder; Entomologist; Plant Physiologist; Plant Pathologist/Virologist; and a Statistician Agronomist, with the West African Cocoa Research Institute—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.197/200/021.

Experimental Officer/Assistant Experimental Officer (Chemist or Chemical Engineer, with H.S.C. (science), H.N.C. in chemistry or chemical engineering, or equivalent qualifications), to assist in the scaling of laboratory syntheses to pilot plant scale—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 1234/34.

Geologist (Geophysics) (with a good honours degree in applied geophysics with geology or physics as subsidiary subjects or a good honours degree in geology with postgraduate training and experience in applied geophysics) with the Federation of Nigeria, to conduct geophysical surveys, chiefly in connexion with ground-water but also with the engineering geology of damn-sites foundations, etc.—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/14/03.

Graduate (preferably in agriculture) to take charge of recording at Cockle Park Experimental Station—The Registrar, King's College, Newcastle-upon-Tyne.

Graduate (with an honours degree in physics, metallurgy or electrical engineering, and some research experience) in the South Wales Laboratories of the British Iron and Steel Research Association Swansea, to develop new processes for continuously applying protective coatings to steel strip at high speeds—The Personnel Officer, B.I.S.R.A., 11 Park Lane, London, W.1, quoting "M.W.C.I.".

Lecturer (with an honours degree in geology) in Economic Geology in the Mining Department—The Secretary, Royal Technical College, Glasgow.

Master to teach Physics—The Headmaster, Christ's Hospital, Horsham.

Mathematical Physicists and Mathematicians, Principal Scientific Officer, Senior Scientific Officer or Scientific Officer grade (with a first- or second-class honours degree in mathematics or physics), to work in one of the following fields: astrophysics, atmospheric diffusion, atomic physics, statistics or stochastic theory, statistical mechanics, reactor physics, fluid mechanics, solid mechanics or general applied mechanics, numerical analysis involving the use of large digital computers—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. B.1019/34.

Principal/Senior Scientific Officer (with a first- or second-class honours degree in chemistry, some research experience, and a sound knowledge of modern analytical techniques as applied to radioactive substances), to work in a team engaged on fundamental research work on radioactive materials (Ref. C.154/34); and a Scientific Officer (with a first- or second-class honours degree in physical or inorganic chemistry and experience in applied research), to carry out applied research in the field of inorganic chemistry in a range of interesting new materials (Ref. 123[illegible]/34)—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting appropriate Ref. No.

Senior Biochemist to the Colchester Group Hospitals—The Group Secretary, Colchester H.M.C., 14 Pope's Lane, Colchester, Essex.

Technician for biochemical and histological research work in the **Rheumatism Research Unit**, Royal National Hospital for Rheumatic Diseases, Bath—The Secretary, Bath Hospital Management Committee, Manor Hospital, Combe Park, Bath.

BRITISH ASSOCIATION MEETING AT SHEFFIELD

Presidential Address : Twentieth-Century Man against Antarctica. By Sir Raymond Priestley 463
Summaries of Addresses of Presidents of Sections 471

3 copies in one minute

Take a document — any document up to $8\frac{1}{2} \times 14$ inches. A document full of complicated data, figures, symbols, sketches. Give it to the 'Verifax' Copier.

In less than one minute you can have three copies . . . *dry* copies, ready for immediate use . . . *photo-accurate* copies, yet produced on non-photographic paper.

Take 50 documents—orders, schedules, invoices, reports, specifications, cost sheets, estimates, contracts— and give them to the 'Verifax' Copier. In less than an hour you can have one, two, three or more copies of every one.

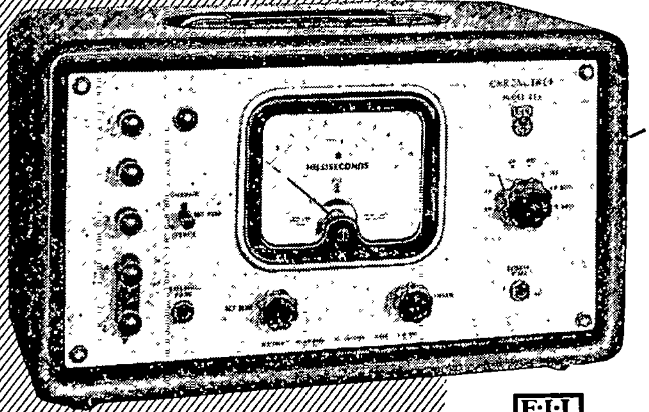
For the 'Verifax' Copier is a fast worker. It is one of the greatest time-savers and money-savers yet introduced into the office. Send for details now, and see what it can save you.

THE *Verifax* COPIER *made by* Kodak

'Verifax' is a registered trade-mark.

Kodak Limited, Dept. 404,
Kodak House, Kingsway, London, W.C.2.

μSECS TO SECS on the new CHRONOTRON



This new version of the well known Chronotron Millisecond Meter has eight ranges and measures time intervals from 100 microseconds up to 10 seconds with an accuracy generally better than 1% f.s.d. The Chronotron is an electronic stop-clock and over 1,000 instruments are in use all over the world, timing relays, switchgear, projectiles, camera shutters and physiological reactions.

ANTARCTICA

SIR RAYMOND PRIESTLEY is the first president of the British Association with personal experience of Antarctica, and very fitting it is that he should be president just before the start of the International Geophysical Year of 1957–58, which has so large an antarctic component. Sir Raymond is truly an elder statesman in antarctic affairs, in that he served as geologist both with Scott and with Shackleton before the First World War, and then proceeded to a notable career in university administration. After Cambridge, Melbourne and Birmingham, happy is it that he should recently have returned, on formal retirement, to leadership of the Falkland Islands Dependencies Scientific Bureau and now to the presidency of the British Association; his presidential address—"Twentieth Century Man against Antarctica"—is printed on p. 463 of this issue of *Nature*.

In the address Sir Raymond sketches in brief the history of Antarctica since 1900. Yet even in this necessarily greatly condensed story, from time to time there peeps through some of the old sparkle and humour which did so much for the morale of those strange ice-cave dwellers of Cape Adare forty-five years ago. Of that remarkable winter story Sir Raymond's modesty now tells us nothing. Like many others, historians delight in the small errors of fact and stress in their colleagues' work, and Sir Raymond will not expect to escape. But the elder statesman's power of panorama is here in full. Of special worth is his incidental comparison of Scott and Shackleton. Would that his friends could persuade him to write a comparative biography of those two great men, for Sir Raymond alone has the scientific knowledge and literary skill, and he served them both. Indeed the pre-1914 antarctic scene is portrayed, though briefly, with a vigour and a percipience perhaps not elsewhere equalled.

That pre-1914 period in Antarctica was the age of achievement despite inadequate techniques—and how inadequate they were was not clear for another decade or two. But the scientific output per unit of effort and money was undoubtedly of a higher order than ever later achieved. The inter-war years on and around the southern continent were decades of rapid advance, when technique at last had ceased to be a limiting factor, and the environment was sufficiently conquered for scientific achievement no longer to be hampered by excessive personal discomfort. In describing this period, Sir Raymond perhaps gives less than their proper due to the vigour, enthusiasm and extent of the Discovery Investigations. Likewise perhaps he remarks too little upon the achievement of the International Whaling Commission, which for all its shortcomings has in fact worked, and has saved alike the whaling industry and the southern whales—at least so far.

The era since the Second World War is more difficult for the historian, and more especially for the scientific historian who, as president of the British Association, knows well that any words of his will set up ripples which may have an influence far beyond his immediate audience and the scientific world. Sir Raymond has, rightly in this presidential address, almost succeeded in avoiding the political problems of Antarctica to-day. The fact of his success must not, however, be allowed to mislead or to act as a soporific to the nation. Sir Raymond does not hesitate to touch lightly upon strategic facts in these days when Suez and Panama are so vulnerable, and the one around-the-world sea route is the southern ocean washing the shores of Antarctica. One wonders if those who work in Foreign Ministries and State Departments would agree that "the fresh resurgence of interest" in connexion with the spectacular activities of the coming International Geophysical Year in Antarctica "has science for its main drive" as Sir Raymond suggests? Perhaps it was true for a short period; but can it still be presumed to be so? Once the national politicians—and let their countries here be nameless—saw the convenience of the scientific cloak, and once a few of the scientists had appreciated the quality of the wicket for extracting national money, the main-spring of antarctic endeavour—so some with knowledge will affirm—became brutally political.

Sir Raymond dilates upon the startling and wonderful scientific efforts which will be made, the myriads of radio-sondes, the rockets and the satellites, the glaciology and the seismology. But with all this he perhaps fails even then to provide a sufficient realization of the real operational magnitude of the many-nationed antarctic endeavours of the next few years. He refers to the £100,000,000 which, it has been estimated, will be spent on this work; but in fact the total cost of the United States effort alone might well exceed that figure. Few members of the British Association will have read the published terms of reference for the United States new antarctic organization, answerable direct to the Operations Co-ordination Board. Science, we can agree, stimulated the "fresh resurgence" in Antarctica; but surely it becomes progressively more difficult to sustain the thesis that the "main drive" is now anything but competitive power politics.

Since in his address Sir Raymond Priestley goes some little way towards assessing the relative achievements of the various nations concerned, it is apposite perhaps to make a comparison. Sir Raymond rightly stresses the British technological failing before the First World War. At that time we failed to perceive the virtues and necessities of dog transport, and the consequences are well known: the Norwegians achieved while we failed. Now again we thrive in the sciences, but once more fail in transport technique in comparison with our rivals in this power-political era. It is an astonishing fact that of the five mutually recognizing sovereign powers in Antarctica (Great

Britain, Australia, New Zealand, Norway and France), not one possesses an icebreaker, without which full manœuvrability around the continental coasts is impossible. Yet Argentina and the United States and the U.S.S.R. are already well provided in this respect. As in the days of Scott and Amundsen, it is to the nation which has the technical benefit of superior transport that goes the prize, whether it be the conquest of the pole, or the long-term foothold in Antarctica. Our science is adequate, our technique of support is not.

The president of the British Association has provided us with an admirable historical background and some little prophecy; but he has rightly felt it out of context to draw the moral beyond the world of science. Yet it is sadly true that, while the scientists admirably co-operate in the excitements of the International Geophysical Year, the nations themselves are fighting in Antarctica a 'cold war' in which material resources are of paramount importance. Whatever may be the outcome of this 'cold war', it seems certain that by the end of the International Geophysical Year scientific knowledge of Antarctica will have made immense strides forward.

GALENUS EXPLICATUS

Galen on Anatomical Procedures

Translation of the surviving books with Introduction and Notes. By Prof. Charles Singer. (Publications of the Wellcome Historical Medical Museum, No. 7.) Pp. xxvi+289. (London: Oxford University Press, 1956. Published for the Wellcome Historical Medical Museum.) 37*s*. 6*d*. net.

THE translation of a work such as this is far from being an uneventful exercise. A knowledge of the language is by no means sufficient, nor does a sympathetic concern in the writer and his work tide the translator over many of his difficulties. It is above all necessary to have a profound knowledge of the subject and of the personality of the author, and it may even be requisite to check his technique and experiments in the laboratory. The diction followed by a worker in the second century A.D. can be very difficult to modernize in another language, largely owing to the lack of an agreed technical vocabulary, and it may be inscrutable unless you have before you a replica of the objective evidence which influenced the original author.

No one knows the difficulties of the task and how to overcome them better than Prof. Singer himself, and the present work has been designed and completed with that knowledge and experience in view. He rightly has a very high opinion of the merits of Galen as an anatomist and physiologist. There is, he says, no comparable work in ancient literature; it established a point of view which was not exceeded for 1,450 years, and it started Vesalius on his triumphant career. A problem which has attracted considerable attention is whether Galen transferred to man anatomical features derived from the dissection of lower animals. In Book 6, Chapter 1 he mentions the types he preferred to dissect as being most like man, but does not admit ignorance of human anatomy. On this question Singer allows that Galen's text "in general is a description of the soft parts of the ape imposed on the skeleton of man". He adds, however: "had Galen any knowledge by dissection of the structure of the human body? I have thought much on this topic, and have several times changed my views, but now think that he had such knowledge. . . . Does Galen ever betray that he has a knowledge of human anatomy reached by direct contact with the object? I now think the answer should be 'Yes'." No further can we get in this ancient and prolonged controversy until fresh contemporary evidence is forthcoming. Moreover, as Singer points out, Galen was heir to five hundred years of physiological research, and yet when he died experimental science too fell dead. "How was it that all this hoarded physiological wisdom of antiquity came to this sudden dramatic end?"

Galen's work on anatomical methods consists of fifteen books, of which only a fragment of the Greek text of Book 9 on the brain has survived. The whole of Books 10–15 lack the Greek originals, and are not included in Singer's monograph; but an Arabic translation of the complete work is now available. It is therefore possible, and certainly desirable, that an English translation and commentary of the Arabic version of the missing Greek Books 9–15 should be undertaken, even though they have played no part in the history of anatomy. An admirable German translation by Max Simon was published in 1906. We must not forget that Galen's value to us is partly his references to the work of his predecessors, much of which would otherwise have remained entirely unknown. On the other hand, he quotes "Hippocrates" thirteen times in the present treatise, and Brasavola's Brobdingnagian index to Galen's Works, which weighs 9 lb. and piles up some 107,000 entries, includes three folio pages of references to the "Hippocratic" corpus, although there is no evidence that Hippocrates himself ever wrote a word of it. Many will be surprised to learn the extent of Galen's knowledge of anatomy and physiology and how accurate it was for his time. He was the last to practise anatomy for many centuries.

Reference to some of the topics known to and studied by Galen may be taken as a cross-section of his morphological activities. The fable that in the crocodile the upper and not the lower jaw is the movable one can be traced back to Herodotus (fifth century, B.C.). It was accepted by Aristotle, Galen, Leonardo, Vesalius, Rondelet, Columbus and Robert Boyle. Oliver Goldsmith claimed in 1772 that it could be established by experiment, and even in 1809 Descourtilz held that the lower jaw could be fixed, and the rest of the entire head moved upwards on the occipital condyle.

Galen did not attempt to dissect small animals, such as insects, but confined himself to vertebrates of all types. His lynx, about which Prof. Singer has some doubts, might well have been *Felis caracal*, which was readily available in number and of a convenient size for examination in the laboratory. These comparative studies led Galen to formulate a teleological explanation of natural phenomena. Hence he says that you can predict the structure of an animal on seeing it for the first time—a possibility exploited by Cuvier in our own era. Galen does not regard the substance of the heart as typical muscle, but that its specific activities accord with the peculiarities of its structure. Pulsation is an intrinsic faculty of the heart and does not proceed from the nerves. The anatomy of the heart and its valves is well described. Nerves can be either sensory or motor and may even be distinguished structurally—a histological truth which could not have been known to Galen. He is interested in the occurrence of an os cordis, and claims to possess a very large specimen of it extracted from the heart of an elephant, where, however, the bone does not normally occur.

Galen must rank as an important experimental physiologist. The statement rife at the time that the arteries do not contain blood he dismisses as "impudent nonsense" worthy of the "comic writers". He then proceeds to demonstrate the falsity of it by observation. His experiments on the physiology of the respiratory movements and on the function of the spinal cord are truly remarkable. On the debit side, however, we have two disastrous errors to record. He believed in the existence of perforations in the ventricular septum of the heart, through which blood could pass direct from the right ventricle into the left, and he assumed that the veins originated in the liver, from which it follows that the flow of the blood in them must be peripheral.

The notes appended to Prof. Singer's volume are the result of unwearied critical research not only in determining the modern equivalents of the muscles, nerves and blood vessels which Galen describes in remarkable detail, but particularly in clarifying and stabilizing the text. Such work is indispensable and beyond praise. Only those of us who have stumbled through Galen's anatomy, dictionary in hand and confusion in mind, can realize how much Prof. Singer has done to lighten the labours of our more fortunate successors.

There is a good index but no bibliography.

F. J. Cole

AN INTRODUCTION TO ASTRONOMY

Introduction to Astronomy

By Dr. Cecilia Payne-Gaposchkin. Pp. x+508. (London: Eyre and Spottiswoode (Publishers), Ltd., 1956.) 50*s*. net.

In the United States much more instruction is given in astronomy than in Great Britain. There it is included in general science courses, and many arts students take short courses of one or two terms in astronomy. Astronomy, which is the oldest of the sciences, is well adapted for teaching as a cultural subject; the history of the development of concepts in astronomy from the early ages to the present time forms a fascinating subject, while the modern investigations into the nature and structure of the universe and the attempts to learn about its beginnings, its evolution and its future have an inherent appeal to the human mind.

Though this introduction to astronomy has been written primarily as an introductory text for American students, it is well adapted for the general reader. The cultural aspect of astronomy has been kept in the forefront of the author's mind and the associations of astronomy with the fields of language, literature and history have been emphasized; little background either in mathematics or physics is required of the reader.

About half the book is devoted to the solar system and half to the stars and stellar systems. The author of a text-book always has to face the problem of the extent to which current ideas, which are still in a state of flux, are to be dealt with. This book gives a well-balanced account of modern views, and the author has pointed out that some of them may require modification or may prove to be quite incorrect. The chapter on variable stars, in which field the author herself has done much work, is perhaps too detailed for an introduction to the subject.

A few errors have been noticed. The statement about Augustus Caesar having taken one day from February to add to August is not correct and should be omitted in any future edition. The number of days in each month have remained as they were fixed by Julius Caesar. Halley spelt his Christian name Edmond, not Edmund as given on p. 145. Greenwich Civil Time, a term used in the United States, is not an acceptable alternative to Greenwich Mean Time; in the summer-months in the United Kingdom the (Greenwich) civil time differs by an hour from Greenwich mean time. Some of the statements about Venus on p. 185 require modification. Venus does not reflect sunlight without changing its colour; Venus is yellower than the Sun. Its light is not white; it is yellower than the light reflected by the Earth. The statement on p. 208 that the spectrum of Jupiter shows some striking features that are common to a greater or less extent to all the major planets, followed by the statement that the dark bands have been identified as molecular spectra of methane and ammonia, is rather misleading, inasmuch as the spectra of Uranus and Neptune contain no bands due to ammonia.

The book is particularly well illustrated with photographs, and there are many text-figures. The series of planetary photographs, taken at the Lowell Observatory, is most valuable; many of the photographs of stars and galaxies were taken with the 200-in. telescope.

H. Spencer Jones

PHYSIOLOGY OF THE MINERAL MINUTIÆ

Trace Elements in Human and Animal Nutrition

By E. J. Underwood. Pp. xi+429. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 9.50 dollars.

It is appropriate that the first book on the nutritional aspects of the trace elements should have been written by an Australian, for some of the most important work on the subject has been done in that country. This is partly the result of the 'challenge', in the sense used by Toynbee in his "Study of History", provided by the diseases of stock on certain Australian pastures, and the response of the scientific workers can only be described as having been an outstandingly successful one. This is not for a moment to suggest that Australia has had a monopoly in trace-element research. Little of the work on iodine, fluorine, molybdenum or manganese has been done there, and the pioneers like Chatin, Raulin, Bertrand, Hart and Ramage were not Australians (a number of them were French); but the work of Bennetts, Underwood and Marston on copper and cobalt has had such enormous economic repercussions that it is impossible not to be impressed by its importance.

In writing this book the author has considered iron, copper, cobalt molybdenum, nickel, zinc, manganese, iodine, fluorine and selenium in some detail, and dealt briefly with aluminium, arsenic, barium, strontium, boron, bromine, silicon and vanadium. His interpretation of the word 'nutrition' has been a very wide one. The chapter on iron, for example, contains the following headings: historical background; the total iron content of the body and its distribution; iron in blood; the forms and amounts of iron in tissues and secretions; absorption; excretion; iron deficiency; requirements for iron; sources of iron in foods and dietaries: references.

It will be seen from this that the physiology of the trace elements would have been a more descriptive title for the book, and people interested in any aspects of the subject would do well to consult it. The whole animal kingdom is really covered, including to some extent the marine invertebrates; but priority has been given to the higher animals including man, and this general approach explains the scanty amount of space devoted to boron, which is only necessary, so far as is known, for plants.

It is a little difficult to pick out the treatment of any one of the elements for special comment, for each of them to which a chapter is devoted is handled in much the same way. Excesses are discussed as well as deficiencies; toxic fluorosis, for example, is accorded full measure.

The last chapter is concerned with the soil–plant–animal relationships of the trace elements. More might have been made of this, for it is just these relationships which make the trace elements so important to human welfare and formed the rationale for the symposium on the subject which was held in the Vatican in 1955.

Judging by the number of times the author has made reference to some of my own somewhat pedestrian publications, the bibliography must be a very complete one. There are omissions, however, here and there. A little more might have been made of fœtal nutrition, for example. There is no record of that curious little creature *Archidoris britannica*, which crawls about the floor of the sea with considerable deposits of calcium and strontium fluoride inside it. If arsenic is worth a mention, it is difficult to see why mercury and lead were not accorded a place; and where is the section on chromium, which seems to be part of the permanent structure of the erythrocyte, whatever its function there may be? But these are trifles, mentioned only to be forgotten. The book is a good one, worth reading from cover to cover; and there is a good author and subject index.

R. A. McCance

CONTROL OF PITUITARY FUNCTION

Neural Control of the Pituitary Gland

By Prof. G. W. Harris. (Monographs of the Physiological Society, No. 3.) Pp. ix+298. (London: Edward Arnold (Publishers), Ltd., 1955.) 30*s*. net.

THE place taken by the hypothalamus in current biological discussion is in striking contrast to its size. This minute region of the brain also remains a happy hunting ground for experimentalists concerned to find in it neural 'centres' for almost every visceral function of the body. Those with which it has already been endowed are more numerous than are its recognizable groups of nuclei; and it is scarcely surprising that some of the latter have had to be invested with the control of very different functions.

Prof. Harris's book, "Neural Control of the Pituitary Gland", is a review of the relationship of this part of the brain to the two main divisions of the pituitary gland. The relationship of the neurohypophysis to the hypothalamus is dealt with in the latter and shorter part of the book. This begins with a brief account of the anatomy of the two structures concerned, and its final chapter focuses on the nature and site of formation of the posterior pituitary hormones, the bias of Prof. Harris's conclusion being that they are elaborated in the neurohypophysis itself. The considerable volume of recent work which has led to the view that the posterior lobe hormones are produced by the nuclei supraopticus and paraventricularis, and that they are transported down the supraopticohypophysial tract into the neurohypophysis, is dealt with in only three pages. The implication of Prof. Harris's cautious reference to this "attractive hypothesis" is that it still remains to be established.

Such reserve does not stamp his treatment of the control of the adenohypophysis. The analysis of this problem begins with the general proposition that the central nervous system "is largely responsible for correlating endocrine activity with that of the other systems of the body, and with the varying requirements of the organism due to environmental change". This statement introduces the further generalization that, with the exception of the neurohypophysis and adrenal medulla, there is no clear evidence that any of the endocrine organs, for example, the thyroid, ovaries and testis, have a secretomotor innervation. The view then emerges that the central nervous system regulates the endocrine organs indirectly by way of a control which the hypothalamus exercises over the anterior pituitary. The latter is effected by means of some undefined chemical substance(s) that is transmitted through the hypophysial-portal vessels, the integrity of which Prof. Harris believes to be essential for normal anterior pituitary function. The "chemotransmitter" then stimulates the pituitary to produce its various trophic hormones, the level of output of which is held in normal balance by a series of interactions with the hormones the secretion of which they stimulate.

The simplicity of this hypothesis is in such striking contrast to the complexity of the pituitary's influence in the body, and with the problems that are implied by the concept of a neural control of the endocrine system, that Prof. Harris's views deepen rather than lighten the mystery that surrounds the physiology of the hypothalamus. Among the many things which the critical reader new to the field needs to be, but is not, told is just what validity can be attached to statements about the precise localization of function in the hypothalamus, when methods of electrical stimulation as well as techniques of making hypothalamic lesions are usually overwhelmingly crude in relation to the size of the neuronal complexes concerned. It is because of this discrepancy that it so often proves impossible to reconcile statements that are made about the exact localization of some presumed hypothalamic functions. A second general point which overshadows this field of experiment is the possibility that many of the responses that are regarded as specific to the hypothalamus, or to some connexion between the hypothalamus and the anterior pituitary, are, in fact, responses which occur as part of a general complex of change that can be initiated by lesions or disturbances which bear no specific relation to either structure. Here it is the essential absence of controls, or of experiments that are carefully designed to test specific hypotheses, which prevents the student from coming to grips with the problems of the hypothalamus. Prof. Harris might have been better advised, therefore, if he had left the problem with the statement, which appears at the start of the general discussion to this section of the book, that the "information as to the details of the mechanism involved is scanty", instead of proceeding to speculations about the number of chemotransmitters that might be involved (when not even a single one has yet been identified), and about the functional differentiation of individual portal vessels in relation to different areas of the anterior pituitary (when it is not yet known that the number, let alone the precise disposition, of the portal vessels in a given species is constant). But if Prof. Harris does not tell us on what "good grounds" he bases this speculation, equally he does not refer properly to experiments that have conclusively shown that whatever influence the hypothalamus exercises over the functions of the anterior pituitary, the pituitary-portal vessels are neither a sufficient nor a necessary explanation of this presumed "control".

Theorizing from slender fact is, of course, one of the ways new fields of biological knowledge develop. But, as in this case, there is always the risk that a single positive observation may emerge which completely undermines an edifice of speculation, and particularly one that has been erected because of an urge to explain the incomprehensible. Publication is these days not infrequently slow, and the danger of a scientific work being somewhat out of date was accentuated in the present case by the fact, noted in the preface, that the book was based on a series of lectures given a few years back.

S. Zuckerman

ARTIST VERSUS SCIENCE

Louis Agassiz Fuertes

Edited by Mary Fuertes Boynton. Pp. xviii+317+17 plates. (London and New York: Oxford University Press, 1956.) 45*s*. net.

To readers who are familiar with the paintings of Louis Agassiz Fuertes, especially those of us who are either painters, naturalists or ornithologists, this book holds much of absorbing interest. But as 'much will have more', it is probable that the need will be felt for additional illustrations to those few given in the book, excellent as they are; especially of those swift field studies and preliminary drawings which are always more intimate and spontaneous, more of the very essence of the artist, than the deliberately planned, finished works.

This book consists mainly of letters from "L.A.G." to his friends and business connexions, and of theirs to him, these being supported, where necessary, by biographical notes. Together they paint a fairly full portrait of the artist, who emerges as a charming, sociable, hard-working person, with a great fund of humour, and obviously beloved by all who knew him.

In a way he was lucky, in that his work was recognized and taken up when he was quite young. He was commissioned by no less an ornithologist than Elliot Coues to paint one hundred illustrations of birds for a book; but one wonders whether this early plunge was in fact good for "L.A.G.", for as an artist he was not mature, and then, as now, the influence of Audubon was a dominant one in American bird portraiture. Had he been granted a few more years of study, it is possible that he would have become aware of the Swedish painter of birds and animals, his contemporary Bruno Liljefors, with his very different æsthetic approach to the work. But, as this book reveals, poor Louis was either so inundated with work of a semi-scientific nature or was away on his travels in foreign parts in search of specimens, that he had no time for artistic experiments, and his style remained, in its essence, a linear one. Because of the dictates of his scientist-patrons his colour did not equal his draughtsmanship, and in spite of all the talk and furore about the effect of light on the plumage of birds, he was forced to present his subjects in a light which was acceptable to the scientist and not in that which emanates from the Sun.

The book is particularly interesting in its account of the hunting expeditions into which "L.A.G." entered with so much zest and excitement, and in which he suffered heat, cold, weariness and illness, meantime killing a prodigious number of birds; these, however, were not wasted, for, fulfilling the purpose for which they were intended, they eventually found their way into museums as mounted specimens or study skins. Interesting too are the letters describing his adventures in landscape painting, these paintings being the preliminary studies for the landscape backgrounds to the dioramas in the American Museum of Natural History.

'Ars longa, vita brevis'; especially was this so in the case of "L.A.G.", for his tragically sudden death occurred while he was still at the height of his powers.

C. F. Tunnicliffe

PRESTRESSED CONCRETE DESIGN

The Theory of Prestressed Concrete Design

Statically Determinate Structures. By Prof. Henry J. Cowan. Pp. xvii+264. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1956.) 36*s*. net.

The title of Prof. H. J. Cowan's book is rather misleading, since it concerns itself almost entirely with beams, with just 12½ pages devoted to pipes and tanks. It can scarcely be said to deal comprehensively with statically determinate structures in general. So far as statically determinate beams are concerned, the book has been written with great care and thoroughness, with numerous worked examples to illustrate points in the text when dealing with design, after a general approach through early chapters on fundamental principles, manufacture, and the properties of steel and concrete.

It is a debatable point whether prestressed concrete design should be carried out these days using working stresses and working loads, with subsequent checks on the load factor at cracking, and at failure. However, having accepted this principle, which permits constant values of Young's modulus for steel and for concrete at the design stage, and permits tension in the concrete, one can appreciate the methods used to get balanced designs for a number of different cases of increasing complexity, and the neat use of diagrams to indicate the range of practical solutions.

Subsequent chapters deal with the load factors against cracking and failure for a number of these, with the effects of cables of varying eccentricity, and with bond, shear and torsion.

In the case of shear, the common error regarding the distribution of shear stress in an 'I' section has unfortunately been perpetuated, but it does not affect the validity of the rest of the work of the chapter, which deals with points very often ignored in books on prestressed concrete design.

If one accepts that design of simply supported prestressed beams should be carried out using working loads and working stresses, the book is a useful and comprehensive text-book; if one believes that design should be based on failure at a definite excess loading, and checked for condition at working loads, it is of far less use. Nevertheless, the chapter on ultimate load still largely applies, as in fact does most of the book except for the work on balanced design, albeit not so conveniently as intended.

References are numerous and well related to the text, and the style of writing is clear and easy to follow. It is well worth a place on the bookshelf for those requiring a detailed study of a specialized structural field. J. W. H. King

AUTOMATION ECONOMICS

The Economic Consequences of Automation

By Dr. Paul Einzig. Pp. xi+226. (London: Martin Secker and Warburg, Ltd., 1956.) 21*s.* net.

THE word 'automation' has become the excuse for a spate of books, articles and speeches, some of which contribute little to the clarification of its meaning. Dr. Paul Einzig's book has all the appearances of having been hurriedly compiled to meet the market, for it quickly abandons the attempt to ascribe to the word any particular meaning and plunges into an exposition of the problems that beset our economy. In this context, automation is merely a synonym for any technical change in methods of manufacture leading to greater productivity, and little attempt is made, except in two chapters at the end which briefly list its advantages and disadvantages, to discuss in detail the specific effects of the introduction of automatic equipment on particular industries or occupations.

Dr. Einzig is more concerned with the general economic problems of inflation, the business cycle and the balance of payments, and the part played in them by any form of labour-saving capital investment; thus there is little in his views that will be new to a reader of the more popular financial journalists. He rightly sees technological change as only one of the possible causes of unemployment, which is itself unlikely so long as expansionist policies continue. The growth of large-scale mass-production industries, in his view, may have a stabilizing economic effect, because of the long periods during which their investment plans mature, although the scale of their production makes them more vulnerable in times of deflationary pressure.

To the better-known reasons for believing that the dangers of the business cycle have been overcome, albeit at the cost of some continuing inflation, Dr. Einzig adds a new one which arises directly out of rising production itself. This is based on the time-lag between the steps taken to increase production, whether by increased employment or overtime or increased capital investment, during which income is generated and the actual production of consumable goods. The effect of this 'pipeline lag' is to keep purchasing power ahead of the volume of goods available to consumers and so to maintain demand. In other words, an increase of capital investment will not, as some economists have feared, cause over-production—although automation (or any other method of raising output by capital investment) may tend to exaggerate deflation during deflationary periods and inflation during inflationary periods.

This argument seems to be in contradiction to Dr. Einzig's view that automation reduces the extent of inflation by raising the output of goods and, by reducing the need for labour in the industries affected, weakening the power of the trade unions to demand wage increases under conditions of "overfull employment".

What is lacking in this analysis is any examination of the problem of the radically different rates of technical advance made possible in the mass-production consumer-goods industries and in the capital-goods industries—a matter of special importance in a country such as Britain, in which the rate of personal consumption at home is going to be more and more dependent on the ability to export capital goods to pay for imported food and raw materials. How are investment and output in these industries to be kept in balance?

Dr. Einzig recognizes that Britain is more likely to suffer from too slow an adoption of new methods than otherwise; but he exaggerates the extent to which, so far, the trade unions have resisted change. In the case of the Amalgamated Engineering Union, he assumes that this is because it is Communist controlled, which it is not. On the other hand, he has some justification for fearing that the narrowing of differentials may be having a harmful effect on the recruitment of the more skilled workers who will be required in industry. He also underlines the inadequate remuneration at present received by research scientists and engineers; but this leads him to the conclusion that a large proportion of them, because of their dissatisfaction with their conditions, are inclined to become Communists or 'fellow-travellers' and that their claims for higher pay must be satisfied in order to secure their political loyalty. Unsupported assertions of this nature must undermine confidence in what purports to be a serious economic study. Austen Albu

SHEFFIELD

Sheffield and Its Region

A Scientific and Historical Survey. Edited by David L. Linton. Pp. xxv+334+11 plates. (Sheffield: British Association for the Advancement of Science, 1956.)*

THOSE attending the annual meeting of the British Association have learned that, in a county justly noted for generosity, the city of Sheffield has played no small part in making Yorkshire hospitality so well known. Before reaching the city, visitors received details of the impressive programme, the varied excursions and the detailed arrangements made for their comfort and convenience. They have also been presented with a copy of a superbly produced book, containing a scientific and historical survey of Sheffield and its region. The book was produced under the general editorship of Prof. D. Linton, of the Geography Department, University of Sheffield, and will give pleasure not only to the recipients but also to all those inhabitants of Sheffield on whose behalf the book has been written for the guidance of visitors from home and overseas.

---

* After the meeting, copies of "Sheffield and Its Region" will be obtainable from A. B. Ward, 24 Chapel Walk, Sheffield. 30*s.*

The potential value of the book emerges from an introduction which has been written with discerning skill. In his introduction the editor shows how the geographical containment of the city has limited and is bound to limit its growth as a regional capital which might be used for the devolution of many of the functions of central government. Yet this city of half a million people, the growth of which has been hindered by the hills around, has great pride in its achievements. This, as is well known, is largely bound up with its steel and cutlery industries; these industries have given the city a community of interest which is probably unparalleled in any city of comparable size in Great Britain.

It is not surprising, therefore, that the story of Sheffield, described in this volume under so many headings, has its origins, in one way or another, either in its great metal-producing and metal-working industries or in the climatic variations which arise from its intricate geomorphological features. The latter are well described in sections prepared by Wilfrid Edwards and Prof. Linton himself. Climatic variations are explained by Dr. Alice Garrett, who, *inter alia*, shows how and why Sheffield must be regarded as one of the snowiest of the large cities of Great Britain.

A study of the Palæolithic, Neolithic and Bronze Ages of the region has been made by A. Leslie Armstrong, who, after describing a number of palæoliths which have been discovered, points out that the "master craftsmen" who made them possessed also "tools and perishable articles of bone, wood and leather". The distinctive feature of the Iron Age in the region is the hill-fort, sixteen of which have been recorded, and the location of which is surveyed by J. E. Bartlett and F. C. Preston; they also describe Roman occupation in the region, a point of special interest being that to-day one steelworks which produces vast quantities of steel is situated on the site of the Roman camp at Templeborough, which is known to have had its own furnaces for making iron.

The history of Sheffield from the age of settlement to more recent times is considered by three of the University's lecturers. One of the places to which visitors are attracted is the field at Dore on the outskirts of Sheffield where, in 829, King Ecgbert of Wessex, having planned to attack Northumbria, was met by King Eanred of Northumbria; Eanred is reputed to have paid homage to Ecgbert. As Mercia was in temporary eclipse to Wessex, some historians are prepared to recognize Ecgbert as the first king of all England; his name is perpetuated in a street at Dore.

One of the most interesting sections in the book is that devoted to the early industrial development of the region. This, by Prof. G. P. Jones, describes primitive forms of metal-working and how, by the late sixteenth century, there were already about a hundred collieries in the West Riding, South Yorkshire and Derbyshire; although most of these were very small, even in 1599 one was producing at the then not inconsiderable rate of 2,000 wainloads a day. Favourable conditions, including ready access to rich supplies of good-quality iron ore, abundance of water-power, and nearness of good materials for making grindstones, led to the continued expansion of cutlery-making and, in 1624, by Act of Parliament the cutlers were made a self-governing corporation; the "Company of Cutlers in Hallamshire" is one of Sheffield's greatest prides.

The second part of this magnificent book is given over to accounts of the economic development of Sheffield, the growth of its social institutions and the great contributions made by the city to the arts and sciences. A picture of Sheffield's Development Plan is painted by the enterprising City Engineer, Henry Foster.

Details of the Sheffield region to-day, including its agriculture, mining and quarrying, steel-making and engineering and lighter trades, and urban centres, are described in the third part of the book, while there are some interesting appendixes on natural history contributed by members of the Sorby Natural History Society. Of the quality of the book it is enough to say that it has been produced by the Oxford University Press and is worthy of that Press.

The story of Sheffield could not have been better presented. If there is an omission, it is that no one has been bold enough to assess the quality and character of the people to-day and of important social developments. Reference is made to the long-sighted efforts of the Bishop of Sheffield, who, more than ten years ago, saw that the parochial system of the Church had to be supplemented if religion were to mean anything in the lives of masses of people in big industrial communities. He founded his industrial mission which has served as a model for similar developments elsewhere. Mention might have been made of the city's extraordinary collection of societies concerned, in one way or another, with better administration and human relations inside industry. Modesty, presumably, explains why no testimonial is given to the devoted work by so many of the region's most influential men to the region's many voluntary organizations. Youth organizations, particularly, have benefited not only by financial support but also by continuing and active personal help. On the cultural side, reference might have been made to the city's weekly visits by the Hallé Orchestra, to its splendid professional repertory theatre which is largely administered by amateurs, and to the Little Theatre, where a distinguished warden has seen that the city does not lack performance of Greek plays.

The quality of the people arises from the character of the city and its industries. Sheffield is a man's city, and the men have been fashioned by centuries of dangerous work, much of it done at night when true fellowship is the more readily built up. The people are long-headed and cheerful. The latter characteristic may spring paradoxically from the grim character of the industrial quarter, since nowhere in Great Britain is there such a trek into the country by walkers and cyclists as pour from Sheffield into Derbyshire at the week-ends. People in Sheffield know that they are close to beautiful countryside; unlike the inhabitants of many similarly placed in other cities, people in Sheffield regularly renew their links with Nature to look down on their city, which a former Vice-Chancellor of the University has said "reminds him of Florence seen from the surrounding hills".

T. H. Hawkins

THE NEUTRINO

By Dr. FREDERICK REINES and Dr. CLYDE L. COWAN, jun.
University of California, Los Alamos Scientific Laboratory, Los Alamos, New Mexico

EACH new discovery of natural science broadens our knowledge and deepens our understanding of the physical universe ; but at times these advances raise new and even more fundamental questions than those which they answer. Such was the case with the discovery and investigation of the radioactive process termed 'beta decay'. In this process an atomic nucleus spontaneously emits either a negative or positive electron, and in so doing it becomes a different element with the same mass number but with a nuclear charge different from that of the parent element by one electronic charge. As might be expected, intensive investigation of this interesting alchemy of Nature has shed much light on problems concerning the atomic nucleus. A new question arose at the beginning, however, when it was found that accompanying beta decay there was an unaccountable loss of energy from the decaying nucleus[1], and that one could do nothing to the apparatus in which the decay occurred to trap this lost energy[2]. One possible explanation was that the conservation laws (upon which the entire structure of modern science is built) were not valid when applied to regions of subatomic dimensions. Another novel explanation, but one which would maintain the integrity of the conservation laws, was a proposal by Wolfgang Pauli in 1933 which hypothesized a new and fundamental particle[3] to account for the loss of energy from the nucleus. This particle would be emitted by the nucleus simultaneously with the electron, would carry with it no electric charge, but would carry the missing energy and momentum—escaping from the laboratory equipment without detection.

The concept of this ghostly particle was used by Enrico Fermi (who named it the 'neutrino') to build his quantitative theory of nuclear beta decay[4]. As is well known, the theory, with but little modification, has enjoyed increasing success in application to nuclear problems and has itself constituted one of the most convincing arguments in favour of the acceptance of Pauli's proposal. Many additional experimental tests have been devised, however, which have served to strengthen the neutrino hypothesis ; and also to provide information as to its properties. The very characteristic of the particle which makes the proposal plausible—its ability to carry off energy and momentum without detection—has limited these tests to the measurement of the observable details of the decay process itself : the energy spectra, momentum vectors and energy states associated with the emitted electron and with the recoiling daughter nucleus[5]. So, for example, an upper limit has been set on the rest mass of the neutrino equal to 1/500 of the rest mass of the electron by careful measurement of the beta-energy spectrum from tritium decay near its end point[6], and it is commonly assumed that the neutrino rest mass is identically zero.

While there is no theoretical reason for the expectation of a finite neutrino rest mass, there is some expectation for a small but finite neutrino magnetic moment of perhaps as much as 10^{-10} Bohr magneton based on a consideration of possible virtual states in which the neutrino may exist effectively dissociated into other particles[7]. An upper limit of $2 \times 10^{-}$ electron Bohr magneton has been set on the magnetic moment by calculations concerning the maximum assignable heat transfer to the Earth by neutrinos from the Sun[8]. We have recently obtained an improved upper limit of 10^{-9} electron Bohr magneton using a large scintillation detector near a fission reactor at the Savannah River Plant of the United States Atomic Energy Commission. The counting rate of single pulses in an energy range of 0·1–0·3 MeV. in 370 gallons of liquid scintillator was observed, and all changes due to reactor power changes were assigned to possible electron recoils in the liquid through magnetic moment interaction with neutrinos. It is hoped that this limit may be further improved by lowering the gamma-ray and neutron background at the detector.

The Pauli–Fermi theory not only requires the neutrino to carry energy and linear momentum from beta-decaying nuclei but also angular momentum, or 'spin'. The simplest of beta-decay processes, the decay of the free neutron[9], illustrates this :

$$n^0 \rightarrow p^+ + \beta^- + \nu_- \qquad (1)$$

As the neutron, proton and beta particle all carry half-integral spin, it is necessary to assign a spin quantum number of 1/2 to the neutrino to balance the angular momenta of equation (1), where any two of the three product particles must be oriented with spin vectors antiparallel. As all four of the particles in equation (1) are, therefore, fermions and should obey the Dirac relativistic wave equations for spin 1/2 particles, there are presumably antiparticles corresponding to each, of which as yet only the anti-electron (or positron) and the antiproton have been identified. The antiparticle corresponding to the neutrino in equation (1) may be obtained by rearrangement of the terms in the following manner :

$$p^+ \rightarrow n^0 + \beta^+ + \nu_+ \qquad (2)$$

This process is observed in positron decay of proton-rich radioactive nuclides where the proton and daughter neutron are both constituent nucleons. Further rearrangement results in the reaction :

$$\beta^- + p^+ \rightarrow n^0 + \nu_+ \qquad (3)$$

This is descriptive of the capture of an electron from one of the inner atomic shells by a nuclear proton and is equivalent to equation (2). The question of the identity of the neutrino, ν_+, appearing in equations (2) and (3) with the neutrino, ν_-, appearing in equation (1) thus arises. With no finite mass or magnetic moment yet measured for either of the neutrinos, one is under no compulsion to assume that they are not in fact identical. The rule of algebraic conservation of fermions, which states that fermions are produced or disappear in particle–antiparticle pairs, requires the ν_- of equation (1) to be named 'antineutrino', since it is emitted with a negative electron. The identity or non-identity of the neutrino, ν_+, and the antineutrino, ν_-, although of no observable significance in single beta decay, should be amenable to test by measurement of the decay constant for double beta decay of certain shielded isotopes. This process was studied theoretically by M. Goeppert-Mayer[10] for the case in which neutrinos are not identical with antineutrinos and by Furry[11] for the case in which the two neutrinos are identical, as proposed by Majorana[12]. Double beta decay is typified by the possible decay of neodymium-150:

$$^{150}\text{Nd} \rightarrow {}^{150}\text{Sm} + 2\beta^{-} + 2\nu_{-} \text{ (Dirac–Mayer)} \qquad (4a)$$

$$^{150}\text{Nd} \rightarrow {}^{150}\text{Sm} + 2\beta^{-} \text{ (Majorana–Furry)} \qquad (4b)$$

If the neutrino and antineutrino are identical, then the virtual emission of one neutrino and its immediate re-absorption by the nucleus are equivalent to the real emission of two neutrinos, and equation (4*b*) is applicable. This cancellation is not possible if the neutrino and antineutrino differ. The half-lives for processes such as equation (4) have been shown by Primakoff[13] and by Konopinski[14] to be quite different in the two cases, of the order 10^{19} years for equation (4*a*) and 10^{15} years for equation (4*b*), where 5·4 MeV. is available for the decay. Furthermore, a line spectrum for the total energy of the two beta particles is to be expected for the Majorana–Furry case (equation 4*b*).

That a decay period consistent with equation (4*b*) does not exist has been shown for a number of shielded isotopes[15], first by Kalkstein and Libby, then by Fireman and Schwartzer for tin-124; by Awschalom for calcium-48; and our associates and us for neodymium-150. In the neodymium-150 experiment, a lower limit of 4×10^{18} years (corresponding to one standard deviation in the background) was set on the mean life against Majorana–Furry decay. This limit is to be compared with a reasonable value on this hypothesis of $1 \cdot 3 \times 10^{15}$ years and one calculated for identical neutrinos (using most severe assumptions) to be 6×10^{17} years. The conclusion remains that the neutrino and antineutrino are distinct particles with an as yet undetected 'difference'. This conclusion is further supported by the negative results of an experiment recently reported by R. Davis[16] employing the reaction:

$$^{37}\text{Cl} + \nu_{+} \rightarrow {}^{37}\text{A} + \beta^{-} \qquad (5)$$

The chlorine target was supplied by 1,000 gallons of carbon tetrachloride placed near a large reactor, and the liquid was tested for the presence of argon-37. Fission fragments, being rich in neutrons, should emit only the antineutrino, ν_{-}.

While careful reasoning from experimental evidence gathered about all terms in the beta-decay process—except the neutrino—may support the inference that a neutrino exists, its reality can only be demonstrated conclusively by a direct observation of the neutrino itself. If the neutrino is a real particle carrying the missing energy and momentum from the site of a beta decay, then the discovery of these missing items at some other place would demonstrate its reality. Thus, if negative beta decays as in equation (1) could be associated at another location with the inverse reaction:

$$\nu_{-} + p^{+} \rightarrow \beta^{+} + {}^{0}n \qquad (6)$$

which is observed to occur at the predicted rate, the case would be closed. An expression for this reaction cross-section has been obtained by application of the principle of detailed balancing to equation (1), knowing the decay constant and electron energy spectrum for the beta decay of free neutrons:

$$\sigma = \left(\frac{G^2}{2r}\right)\left(\frac{\hbar}{mc}\right)^2\left(\frac{p}{mc}\right)^2 \frac{1}{(v/c)} \text{ (cm.}^2\text{)} \qquad (7)$$

where σ is the cross-section in cm.^{2}; G^2 ($= 44 \times 10^{-24}$) is the dimensionless lumped beta-coupling constant based on neutron decay[9]; and p, m and v are the momentum, mass and speed of the emitted positron, respectively c is the speed of light, and $2\pi\hbar$ is Planck's constant, all in c.g.s. units. For neutrinos of 3-MeV. energy incident on free protons, this cross-section is 10^{-43} cm.^{2}. Explicit solution of equation (6) for the cross-section as a function of the neutrino energy yields:

$$\sigma = 1 \cdot 0 \times 10^{-44} \times (E - a) \sqrt{(E-a)^2 - 1} \text{ (cm.}^2\text{)} \qquad (8)$$

where $a + 1$ ($= 3 \cdot 53$) is the threshold for the reaction and E is the neutrino energy, both in units of $m_e c^2$. The threshold for a proton bound in a nucleus is higher by an amount equal to the energy difference between the target and daughter nuclei. It is interesting to note that the penetrability of matter is given by equation (8) to be infinite for neutrinos with low energies ($E < a + 1$) and is very large for neutrinos of only a few MeV., the mean free path for absorption being measured in the latter case in terms comparable to the radius of the universe.

Equation (6) may be employed in an experiment in which a large number of hydrogen atoms are provided as targets for an intense neutrino flux and are watched by a detector capable of recording the simultaneous production of a positron and a neutron. Such a direct experiment is made possible by the availability of high beta-decay rates of fission fragments in multi-megawatt reactors and advances in detection techniques through the use of liquid scintillators. An estimate of the neutrino flux available from large reactors shows that a few protons should undergo reaction (6) per hour in 50 litres of water placed near the reactor. The problem, then, is to observe these events with reasonable efficiency against the background of reactor neutrons and gamma-rays, natural radioactivity and cosmic rays. In an experiment conducted at the Hanford Plant of the Atomic Energy Commission by us[17] in 1953, an attempt was made in this direction. The target protons were supplied by 300 litres of liquid scintillator (toluene plus trace amounts of terphenyl, and alpha-naphtha-phenyloxayole in which cadmium propionate was dissolved). A delayed coincidence-rate of pairs of pulses, the first of each pair being assignable to the positron and the second to a neutron capture in cadmium, of 0·4 ± 0·2 counts per minute was observed, in agreement with the predicted rate, and with a large reduction in the backgrounds mentioned above. The signal-to-total-background ratio, however, was still very low (1/20), rendering further testing of the signal impractical and leaving the results tentative. On the basis of the Hanford experience it was felt that the detection problem was soluble in a definitive manner, and a second experiment was designed[18] with the view of further reduction of backgrounds and providing means for checking each term of equation (6) independently.

Fig. 1 is a schematic diagram of the detection scheme employed in this experiment. The sequence of events pictured is as follows: a neutrino from the decay of a fission fragment in a reactor causes a target proton to be changed into a neutron with the simultaneous emission of a positron. The positron is captured by an electron in the target water, emitting two 0·51-MeV. annihilation gamma-rays, which are detected simultaneously by counters I and II. The neutron moderates and diffuses for several micro-

seconds and is finally captured by the cadmium giving a few gamma rays (totalling 9 MeV.), which are again detected by I and II. Thus we have a prompt coincidence followed in several microseconds by a second prompt coincidence, providing a very distinctive sequence of events.

The over-all size of the equipment was set by the number of events expected per hour per litre of water, and the detection efficiency one could hope to achieve. A primary factor in the design geometry and detection efficiency was the absorption of the positron annihilation radiation by the target water itself. Experimentation and calculations showed that an optimum water thickness was 7·5 cm. Since the over-all efficiency dictated a target volume of about 200 litres to yield several counts per hour, two target tanks were used, each measuring 1·9 m. × 1·3 m. × 0·07 m. The depth of the liquid scintillation detector (61 cm.) was such as to absorb the cadmium-capture gamma-rays with good efficiency and transmit the resultant light to the ends of the detector with minimal loss. The scintillating liquid (triethylbenzene, terphenyl and POPOP wave-length shifter) were viewed from the ends of each detector tank by 110 5-in. Dumont photomultiplier tubes, a number determined primarily by the amount of light emitted in a scintillation. The complete detector consisted of a 'club sandwich' arrangement employing two target tanks between three detector tanks, comprising two essentially independent triads which used the centre detector tank in common. The entire detector was encased in a lead–paraffin shield and located deep underground near one of the Savannah River Plant production reactors of the United States Atomic Energy Commission. Signals from the detectors were transmitted via coaxial cables to an electronics trailer located outside the reactor building. The pulses were analysed by pulse-height and time-coincidence circuits and, when acceptable, were recorded photographically as traces on triple-beam oscilloscopes. Fig. 2 is a record of an event in the bottom triad. The entire system was calibrated using a plutonium–beryllium neutron source and a dissolved copper-64 positron source in the target tanks; and standardized pulsers were used to check for stability of the electronics external to the detector itself. The response of the detector to cosmic ray μ-mesons was also employed as a check on its performance. After running for 1,371 hr., including both reactor-up and reactor-down time, it was observed[19] that:

(1) A signal dependent upon reactor-power, 2·88 ± 0·22 counts/hr. in agreement with the predicted[20] cross-section (6×10^{-44} cm.^{2}), was measured with a signal-to-reactor associated accidental background in excess of 20/1. The signal-to-reactor independent background ratio was 3/1.

(2) Dilution of the light water solution in the target tank with heavy water to yield a proton density of one-half normal caused the reactor signal to drop to one-half its former rate. The efficiency of neutron detection measured with the plutonium–beryllium source was unchanged.

(3) The first pulse of the pair was shown to be positron annihilation radiation by subjecting it to a number of tests: its spectrum agreed with the spectrum of positron annihilation radiation from copper-64 dissolved in the water, and it was absorbed in the expected manner by thin lead sheets inserted between the target tank and one detector.

(4) The second pulse of the pair was identified as due to the capture in cadmium of a neutron born simultaneously with the positron by virtue of its capture-time distribution as compared both with calculations and observations with a neutron source. The second pulse spectrum was consistent with that of cadmium-capture gamma-rays, and removal of the cadmium resulted in disappearance of the reactor signal.

(5) Reactor-associated radiations such as neutrons and gamma-rays were ruled out as the source of the signal by two kinds of experiment. In the first, a strong americium–beryllium neutron source was placed outside the detector shield and was not only found very inefficient in producing acceptable delayed coincidences but was also found to produce a first-pulse spectrum which was unlike the required signal in that it was monotonically decreasing with increasing energy. In the second experiment an additional shield, which provided an attenuation factor of at least 10 for reactor neutrons and gamma-rays, was observed to cause no change in the reactor signal outside the statistical fluctuations quoted in (1).

Completion of the term-by-term checks of equation (6) thus demonstrated that the free neutrino is observable in the near vicinity of a high-power fission reactor.

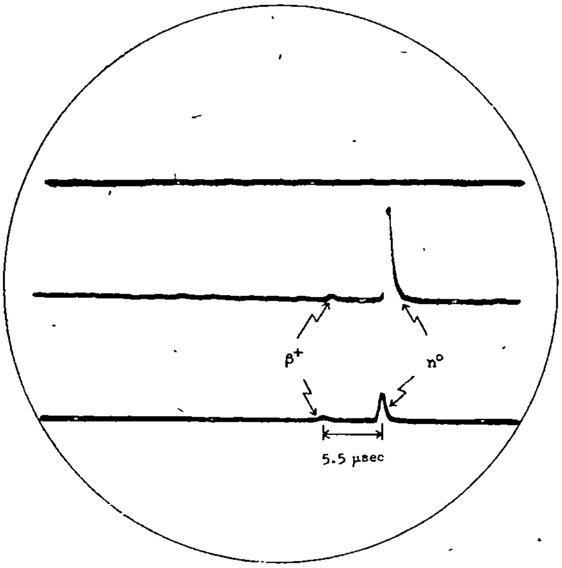

Fig. 2. A characteristic record. Each of the three oscilloscope traces shown corresponds to a detector tank. The event recorded occurred in the bottom triad. First seen in coincidence are the 'positron' annihilation gamma-ray pulses in each tank followed in 5·5 μsec. by the larger 'neutron' pulses. The amplification was chosen in this case to enable measurement of the neutron pulses. A second oscilloscope with higher amplification was operated in parallel to enable measurement of the positron pulses

The availability of neutrinos from reactors in sufficiently intense fluxes has opened a number of interesting possibilities. One arises from the use of heavy water to dilute the proton target as described above. This test was valid because the threshold for the neutrino interaction with the deuteron is higher by 2·2 MeV., the binding energy of the deuteron, than the threshold energy for equation (6), and the cross-section is for this reason an order of magnitude smaller; other considerations reduce it still further. The neutrino–deuteron interaction is itself, however, of interest, as two alternatives arise:

$$\nu_- + D \rightarrow \beta^+ + n + n \qquad (8a)$$

$$\nu_- + D \rightarrow \beta^+ + n_2 \qquad (8b)$$

where n_2 is the bound state of the bineutron[21], as yet unobserved. If reaction (8*a*) were observed to occur, then a careful measurement of its rate relative to the rate of reaction (6) and a knowledge of the fission neutrino spectrum should enable a direct determination of the ratio of the Fermi and Gamow–Teller coupling constants in beta decay. This follows from the fact that the coupling constant in equation (6) includes a mixture of both types, whereas in (8*a*) it is composed of the Gamow–Teller constant alone. If, on the other hand, equation (8*b*) were observed, not only would these considerations hold, but also the existence of a bound state of the bineutron, which would necessarily be a singlet state (antiparallel spins) because of the Pauli exclusion principle, would bear directly on the question of the dependence of nuclear forces on charge. This follows because the singlet state of the (n, p) system is known to be unbound. As the two neutrons in equation (8*a*) can possess only a few kilovolts of energy when produced by fission-fragment neutrinos, and as they leave the event in antiparallel spin states, the conditions seem favourable for the formation of bineutrons, even if the binding energy were only tens of kilovolts.

Since the proposal of the neutrino hypothesis by Pauli and its success in Fermi's theory of nuclear beta decay, the particle has been called upon to play similar parts in the observed decay of a number of different mesons[22]. The question arises as to the identity of these neutrino-like particles with the neutrino of nucleon decay. It is to be noted that in nuclear beta decay the initial and final nuclei both quite obviously interact strongly with nuclei. This is not the case in (π, μ) decay, where the emission of a 'neutrino' converts the interaction of the heavy particles with nuclei from strong to weak. Furthermore, despite the apparent equality of the nuclear beta-decay matrix elements with those associated with (μ, β) decay, both the initial and final products of the latter interact weakly with nuclei.

The neutrino is the smallest bit of material reality ever conceived of by man; the largest is the universe. To attempt to understand something of one in terms of the other is to attempt to span the dimension in which lie all manifestations of natural law. Yet even now, despite our shadowy knowledge of these limits, problems arise to try the imagination in such an attempt. If nuclear reactions played a part in a cataclysmic birth of the universe as we assume, what fraction of the primordial energy was quickly drained into the irreversible neutrino field? Are these neutrinos—untouched by anything from almost the beginning of time—trapped by the common gravitational field of the universe, and if so, what is their present density, their energy spectrum and angular distribution? Do neutrinos and antineutrinos exist in equal numbers? If the neutrino has zero rest mass, is it to be considered with 'matter' particles in discussing its gravitational potential, or with electromagnetic radiation? The problem of detecting these cosmic end-products of all nuclear energy generation processes and the measurement of their characteristics presents a great challenge to the physics of to-day.

The known properties of the neutrino are summarized below.

PROPERTIES OF THE NEUTRINO

Spin: $1/2\hbar$.
Mass: $< 1/500$ electron mass, if any.
Charge: 0.
Magnetic moment: $< 10^{-}$ Bohr magneton
Cross-section for reaction: $\nu_- + p^+ \rightarrow \beta^+ + n^0$ at 3 MeV. $= 10^{-43}$ cm.^{2}.
Neutrino ν_+ not identical with antineutrino ν_-

Our work and that of our associates reported in this paper were supported by the United States Atomic Energy Commission.

NUCLEAR COOLING

By DR. N. KURTI, F.R.S., DR. F. N. H. ROBINSON*, SIR FRANCIS SIMON, C.B.E., F.R.S., and D. A. SPOHR

The Clarendon Laboratory, Oxford

IN various laboratories temperatures of the order of 1 millidegree above absolute zero have been reached by the magnetic cooling method using the isentropic demagnetization of an electron paramagnetic substance. The lowest temperature which may usefully be reached in this way is limited by the presence of interactions (dipole–dipole, exchange, etc.) between the electron spins. Soon after the first successful magnetic cooling experiments it was suggested[1,2] that by demagnetization of nuclear spins much lower temperatures might be reached at which the nuclear spins would become ordered.

The feasibility of nuclear demagnetization experiments was discussed in some detail in 1939 by Simon[3]. He pointed out that, in order to remove an appreciable part of the nuclear entropy, field and temperatures of the order of 50 k.gauss at 0·01° K. would be necessary.

The first step in a nuclear cooling experiment is to magnetize, that is polarize, the nuclear spins. Halban[4] directed attention in 1937 to the possible utility of oriented nuclear systems in the study of nuclear reactions, and Spiers[5] calculated the angular distribution of emissions to be expected from oriented radioactive nuclei. Since such experiments do not necessitate demagnetization, use could be made of atomic and molecular fields for orienting the nuclei. Various methods have been proposed and used experimentally; an account will be found in the review article by Ambler and Hudson published in 1955[6]. More recently, indium nuclei have been polarized using an external magnetic field by Dabbs, Roberts and Bernstein[7] (1955). From these diverse experiments information about the spins and parities of excited states of about a dozen nuclides have been obtained.

As a result of these successful applications, work on nuclear demagnetization at the Clarendon Laboratory has, since the pioneer experiment of Hatton and Rollin in 1949[8], been understandably relegated to second place. Those authors demagnetized a crystal of calcium fluoride from a field of 4,000 gauss at 1·2° K. to 500 gauss. The temperature of the fluorine nuclear spin system was deduced from the strength of a nuclear resonance signal, and was observed to fall to 0·17° K., rising to 1·2° K. with a relaxation time (spin–lattice) of 60 sec. In their experiment, however, the entropy removed from the nuclear spin system was extremely small (10^{-4} per cent) compared with the entropy content of the lattice, and so no appreciable cooling of the system as a whole could result. The same consideration also applies to the ingenious series of experiments described in 1951 by Pound, Purcell and Ramsey[9].

More recently, interest has been renewed in the problem, and we have made some progress towards the realization of our aim, which is to effect an appreciable reduction of entropy in a nuclear spin system by an external magnetic field, and so to obtain information about nuclear interactions in solids by measuring the temperature reached on subsequent demagnetization.

Nuclear cooling involves the following steps. The nuclear paramagnetic substance is magnetized in a large field and the heat of magnetization absorbed by a thermal sink at 0·01° K. or thereabouts. The field is then reduced to zero, when if the process occurs adiabatically the nuclear spins cool to a temperature determined by the initial temperature, the applied field and the nuclear interactions.

A heat sink at 0·01° K. can only be an electron paramagnetic material which has been previously demagnetized (from a few tens of k.gauss at about 1° K.) to practically zero field. It must necessarily be some way away from the nuclear specimen if the latter is to be magnetized. Daniels[10] has designed a water-cooled solenoid capable of producing fields adequate for nuclear demagnetization and so arranged that, 23 cm. away from the centre of the coil, the field is reduced to less than 0·1 per cent over a region large enough to accommodate the heat sink. This magnet was used in the experiments to be described.

In order for the heat of magnetization of the nuclei to be transferred to the heat sink in a reasonable time (say, less than half an hour), it is first of all necessary that the nuclear spin–lattice relaxation time be short enough. This is most easily achieved by using a metal, since it is known[8,11] that in metals this time is of the order of seconds at 1° K. and can be expected to be of the order of minutes at 0·01° K.

It is, however, essential, if a metal is used, to take precautions to prevent eddy-current heating of the specimen due to ripple fields and to the changing flux on demagnetization. The former can be avoided to a certain extent by using a very smooth d.c. source to energize the magnet and by placing a thick copper screen around the cryostat. The latter can only be avoided by subdividing the specimen into a large number of insulated segments. To indicate the importance of these precautions: the total heat of nuclear magnetization for a solid copper cylinder 1 cm. in diameter and 5 cm. long in a field of 30 k.gauss at 0·01° K. is of the order of 10^3 ergs, while the heat generated in the cylinder during the reduction of this field to zero in two minutes is about one hundred times this value.

Kurti[12] has discussed various types of heat link, and concluded that a copper link of reasonable dimensions would give adequate heat transfer. Copper is not only readily available as thin insulated wire but also has desirable nuclear properties (see, for example, ref. 3). It is therefore convenient to use copper both in the heat link and in the nuclear stage itself. The latter can then be made simply as an extension of the link.

Heat transfer from the link to the paramagnetic salt constituting the sink, and stray heat influxes to the specimen, have been the two major stumbling blocks in this research.

It is known[13,14] that the heat flow between copper fins and a pressed paramagnetic salt in contact over the macroscopic area A can be expressed by the equation:

$$\dot{Q} = \alpha A(T_1^3 - T_2^3) \qquad (1)$$

---

* English Electric Research Fellow.

where T_1 and T_2 are the temperatures on the two boundary surfaces, and α is of the order of 10^3 ergs cm.$^{-2}$ deg.$^{-3}$ sec.$^{-1}$. Since we wished to transfer quantities of heat of the order of 1,000 ergs in a few minutes at about 0·01° K., it is clear that the area of contact must be several hundred square centimetres. Early attempts by Robinson to achieve such a heat transfer using powdered chrome potassium alum compressed about copper fins or wires failed. It was comparatively easy to achieve areas of contact of the order of 10–50 cm.^{2} which were adequate at temperatures above 0·1° K., but it was found mechanically impossible to increase this area greatly. Robinson[15] found, however, that if the alum were made into a slurry with a mixture of glycerol and water, it was possible to obtain the same degree of thermal contact as is represented by equation (1) *without* applying pressures. It is then feasible to make an assembly of a paramagnetic salt having a relatively complex fin or wire system embedded in it and thus to obtain a large area of contact. Using this technique, Kurti and Spohr have constructed a specimen and used it in the experiment now to be described. (This experiment constitutes part of a D.Phil. dissertation to be presented by D. A. Spohr to the University of Oxford.)

A photograph of the specimen and cradle is reproduced in Fig. 1, together with a schematic diagram of the essential features. The heat link connecting the top and bottom pills consists of 1,540 enamelled copper wires (40 S.W.G.) embedded uniformly at their top ends over the cross-section of a glycerol-chrome potassium alum slurry (of about 16 gm.) enclosed in a 'Perspex' container. The contact area between the metal and the slurry was calculated to be 400 cm.^{2}. At the lower ends the wires are folded over four times in a length of about 7 cm. to form the nuclear 'specimen', which thus contains approximately 0·75 gram atom of copper.

In this preliminary experiment, no heat switch was used between the stages. The contact resistance between the link and the paramagnetic salt, together with the expected spin–lattice relaxation time, made it possible to measure nuclear temperatures after demagnetization and before the nuclear system warmed again to the temperature of the heat sink, a process which took two to three minutes.

The assembly shown in the photograph was mounted inside a loosely suspended 'capsule' consisting of a double-walled brass tube, the top part of which contained 25 gm. of manganous ammonium sulphate, cooled by demagnetization at the same time as the chrome alum pill. The bottom part of the capsule surrounding the nuclear stage was kept in good thermal contact with the manganous salt by means of liquid helium and by thin copper wires running longitudinally between the brass walls. The purpose of the capsule was to reduce stray heat influxes into the system due to vibration, gas recondensation and conduction down the glass suspensions. Prior experiments with the capsule and with a specimen in which the folded-up nuclear stage was replaced with a pill of cerium magnesium nitrate (used as a magnetic thermometer) indicated that the heat influx to the bottom of the link was about 1 erg per min. The same experiments also showed that 10 min. after demagnetization of the heat sink, the lower end of the heat sink had reached 0·011° K. From the slope of the cooling curves and the known heat capacity of the cerium salt, it was possible to deduce that the heat transfer between the salts and the link was approximately that predicted by equation 1.

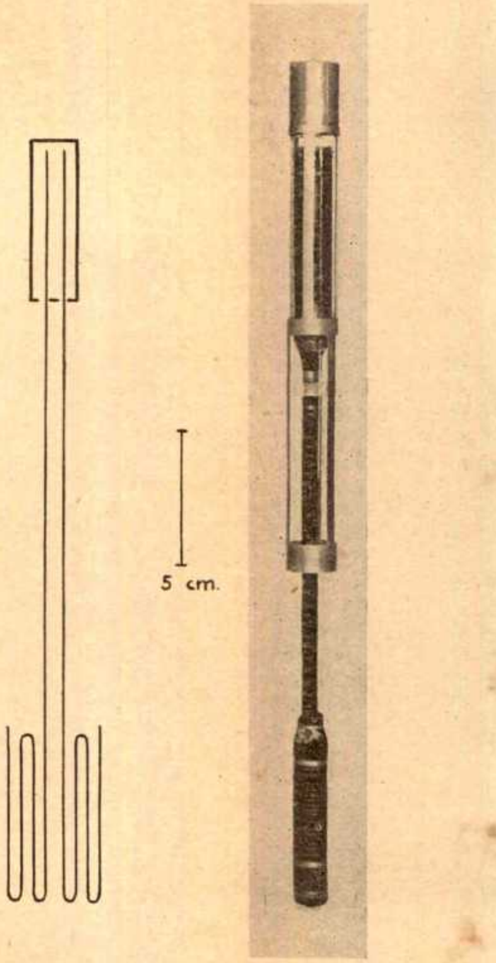

Fig. 1. Heat sink, heat link and nuclear specimen in cradle

The temperature of the nuclear spin system was obtained from ballistic measurements of its susceptibility, assuming that the latter obeyed Curie's law. The calibration of the system was calculated from the theoretical nuclear susceptibility of copper ($\chi = \frac{3 \cdot 74 \times 10^{-7}}{T}$ per gram atom) and from the sensitivity of the measuring circuit. This was determined by measurements at liquid-hydrogen temperature of a specimen of manganous ammonium sulphate of the same size as the nuclear stage. The sensitivity can be expressed by the equation :

$$\delta_N = 3 \cdot 4 \times 10^{-5}/T \text{ cm.} \qquad (2)$$

for a reversal of the primary field of 7·8 gauss.

Unfortunately, it was not also possible to calibrate the ballistic system in the conventional way by observing the galvanometer deflexion at various known temperatures above 0·01° K. This was partly because of the extremely small value of the nuclear susceptibility in this calibration range, and partly because *at these temperatures* the nuclear susceptibility is masked by a susceptibility probably arising from paramagnetic impurities in the copper wire (cf. ref. 16), and insulation. The interpretation of the ballistic measurements is also complicated by the proximity of a large mass of paramagnetic material in the heat sink and capsule. The effect of this and of the paramagnetic impurities on the measured susceptibility was determined by a control experiment in which the nuclear stage was located outside the influence of the primary field.

In the nuclear cooling experiment, the electronic stage (sink) was first cooled by demagnetization from approximately 1° K. and 20 k.gauss to about 0·01° K. The nuclear stage was then slowly magnetized in fields of up to 28 k.gauss. The resulting reduction of entropy for this field was about 1 per cent of the total nuclear entropy of 2·8 cal./deg./gram atom. The field was maintained at its full value for various times ranging from 5 to 20 min. and then reduced to zero at a rate of between one-half and one k.gauss per sec. Readings of the ballistic deflexion were taken at about 10-sec. intervals starting some 13 sec. after the field had reached zero.

Fig. 2 shows the deflexion δ_N obtained for a field reversal of 7·8 gauss as a function of the time after complete demagnetization. The corresponding values of T calculated by equation 2 are also indicated. The different curves correspond to different values of the initial field as given in Table 1. By extrapolating these curves back to zero time, an estimate of the magnetic temperature reached immediately after demagnetization can be obtained. It will be seen that, using the largest field, this is about 20×10^{-6} °K.

It has already been mentioned that paramagnetic impurities might contribute a susceptibility of the same order as that due to the nuclei. It is, nevertheless, unlikely that the large relative changes in susceptibility after demagnetization could be due to that cause. For such large deflexions to occur, the electron paramagnetic would have to behave very nearly ideally, and even then one would not expect any appreciable change in the entropy (that is, a further increase in deflexions) for values of H/T larger than about 50 k.gauss per deg. (The difference in heat of magnetization for a gram atom of a perfect electron paramagnetic between $H/T = 300$ and $H/T = 2{,}300$ kgm./deg. is 10^{-9} ergs at 0·012° K.) Fig. 2 shows, however, that progressively lower temperatures were reached for values of H/T of up to 2,300 k.gauss per deg.

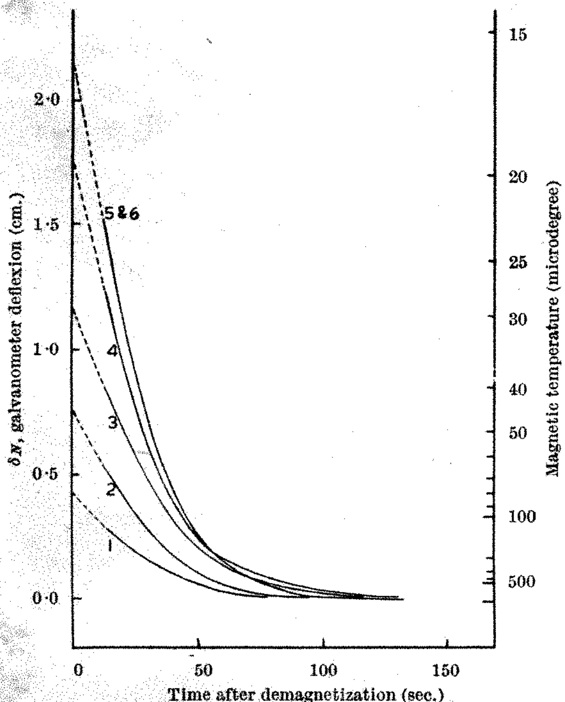

Fig. 2. Ballistic deflexion and temperature of nuclear stage after demagnetization

As it can be assumed that Curie's law is obeyed even at the lowest temperatures during this experiment, then one can estimate the magnitude of the temperature θ_N characterizing the nuclear interactions[8]. If T_i is the initial temperature, H_i the field before demagnetization, and T_f the temperature reached immediately upon demagnetization, then θ_N is given by:

$$\theta_N = T_f \frac{\mu H_i}{kT_i} \tag{3}$$

where μ is the nuclear moment. Assuming that $T_i = 0{\cdot}012°$ K., and using the dotted line extrapolations in Fig. 2 to estimate T_f, one obtains the values given in Table 1 for the different curves shown in Fig. 2.

Table 1

No of curve.	1	2	3	4	5	6	
Initial field	3·48	6·95	10·4	13·9	20·9	27·8	k.gauss
$\theta_N \times 10^6$	1·94	2·18	2·11	1·87	2·26	3·00	

It will be seen that the results are in rough agreement from run to run. The average value of θ_N, namely, $2{\cdot}3 \times 10^{-6}$ °K., may be compared with the calculated value for the temperature of the nuclear co-operative anomaly in copper (4×10^{-6} °K.) given by the theory of Fröhlich and Nabarro[17].

From the present experiment it is not possible to decide whether the conduction electrons and the lattice also participate in the cooling. The rate of warming up is compatible with both the estimated nuclear spin–lattice relaxation time and the heat transfer coefficient between the nuclear stage and the heat sink. There are two arguments in favour of the hypothesis that the electrons participate in the cooling process, and thus, that there is a thermal equilibrium established in the whole specimen (the lattice in any event has a negligible thermal capacity). One is that if the cooling and subsequent warming up were due to nuclear spins only, then δ_N (or $1/T$) would be a linear function of time by virtue of the dependence of the nuclear specific heat on $1/T^2$. As can be seen from Fig. 2, that is not so (at least at the higher temperatures) and the curves indicate a heat capacity increasing with temperature. Further, the mechanism which produces the co-operative anomaly considered by Fröhlich and Nabarro involves the participation of the electron spins. If that were not the case, the expected anomaly would occur at a much lower temperature ($\sim 10^{-7}$ °K.) in contradiction to the value estimated from these results.

These experiments have shown that by using nuclear demagnetization one can reach temperatures below those accessible with electron paramagnetics. They also furnish direct evidence of the interactions between nuclei in metals. We have therefore thought it worth while to describe these first exploratory experiments, which we hope in due course to improve by the use, for example, of a heat switch, and also to extend to materials other than copper. It should be emphasized that the importance of this type of experiment is not so much in the lowness of the temperature achieved, but rather in the information we may hope to gain about the behaviour of nuclear spins in solids and their interaction with their environment.

BIOLOGICAL HAZARDS OF NUCLEAR AND OTHER RADIATIONS

By Dr. C. AUERBACH

THE dangers of ionizing radiation to human health have long been recognized by a small circle of experts. The early radiologists had to pay a tragic toll of death and disease for their ignorance of the cellular damage caused by radiation, and geneticists, foremost among them Muller, have for many years warned against the much less obvious, but in no way less real, danger to future generations. Only during the past year or two has a wide public become disturbed about the biological effects of ionizing radiation because of their connexion with nuclear fission. Fantastic over- and under-estimates of these effects have appeared in the popular press and have been used as ammunition in the war of opinions between those who oppose and those who support the continuation of atom and hydrogen bomb tests. The more sober and cautious statements of the biologists themselves tend to be regarded with suspicion as being biased by political convictions. It is therefore greatly to be welcomed that authoritative digests of scientific experience and opinion have been prepared and published independently in Great Britain and the United States*. The British report has been commissioned by the Government, the American one by the National Academy of Sciences. Both have been prepared by leading authorities in physics, medicine, genetics and allied fields, the British one by a committee appointed by the Medical Research Council, the American one by six separate committees dealing with the impact of radiation on genetics, pathology, meteorology, oceanography and fisheries, agriculture and food supplies, disposal and dispersal of radioactive wastes. The American report thus covers a very wide field, including such questions as the possible influence of atomic bomb tests on the weather or the use of isotopes in agricultural and oceanographic research, while the British report, after an introductory chapter on the nature of radiation and its action on living cells, is concerned only with the proved or possible effects on the individual, his immediate progeny, and future human populations.

Although only the British report indicates in its title that nuclear fission is not the sole source of ionizing radiation, it is clear from both reports that the present dangers arise much more from excessive use of X-rays than from bomb fall-out or from atomic energy establishments. Thus, ironically, the public anxiety about nuclear weapons has resulted in reports which emphasize long-neglected dangers in medical practices. In Britain, X-ray diagnosis, mainly of hip, lumbar spine, lower abdomen and pelvis, adds at least 22 per cent and possibly much more to the average amount of natural radiation (3 r.) which the gonads receive during the genetically important period from conception to thirty years. In the United States X-rays are estimated to add 3r. to a background radiation of 4·3r. Even allowing for the facts that this figure includes therapeutic as well as diagnostic X-rays and may represent a maximum compared with the British minimum, this amazingly high contribution of X-rays to the gonad dose of the average American reflects the excessive use of X-rays in that country. Both reports agree in considering the present level of ionizing radiation due to nuclear fission as negligibly small, and in estimating that this level would rise to about 1 per cent of the normal background radiation, if nuclear weapon testing should continue at the present rate. The formidable technical problems which even in the near future will be posed by the accumulation of radioactive waste are brought home by the forecast that in 1965 nuclear reactors in the United States will be producing somewhat more than 10 kgm. of fission products per day.

The hazards to the exposed individual himself are negligibly small when accidents or nuclear warfare are excluded. A shortened expectation of life through accumulated low doses of radiation, which is mentioned in the British report only as a hitherto unproved possibility, is suggested by American data on the comparative life-spans of radiologists and other physicians. Repeated exposure to doses which are individually harmless may increase the incidence of leukaemia, as shown by a follow-up of British patients who had received prolonged X-ray treatment for ankylosing spondylitis. The British report recommends, therefore, that no individual should receive more than 200 r. of total body radiation, spread over tens of years, and that the maximum weekly exposure, averaged over any period of thirteen consecutive weeks, should not exceed 0·3 r. Among fission products likely to be ingested only strontium-90, which is retained in the bone, may constitute a danger, but its present level is negligibly low.

The Biological Effects of Atomic Radiation: Summary Reports from a Study by the National Academy of Sciences. Pp. xiv+108. (Washington, D.C.: National Academy of Sciences—National Research Council, 1956.).

For a calculation of the genetically permissible dose, as distinguished from that which is harmless to the individual, new considerations become relevant. Not only is the genetical material by far the most radiosensitive part of the organism; the linear increase of mutation-rate with dose and the absence of a lower threshold make the exposure of many individuals to very small doses genetically as dangerous as that of a few individuals to large ones. There is, in fact, no innocuous dose from the genetical point of view, and the permissible dose-level has to be reached by a compromise between the immediate benefits of ionizing radiation and the damage to future generations. We still lack the data for an even moderately accurate quantitative estimate of the genetical effects of a given dose on human genes. Calculations use extrapolations from experiments on lower animals and include premises on which geneticists differ among themselves.

It is therefore encouraging to find a considerable measure of agreement between the conclusions of the British and American geneticists. Both estimate that the doubling dose, that is, the dose which would double the mutation-rate, lies most probably within the range from 30 r. to 80 r. In the final result, this dose would double the incidence of genetically caused defects; but for recessives this may take a very great number of generations. American geneticists estimate that the effect on the first generation of doubling the gonad dose would consist in an additional 200,000 cases of genetically caused tangible disabilities among 100 million births. In Great Britain, 200 more cases each of manic depressive insanity and schizophrenia and 1,500 of severe mental deficiency would be expected among the first generation of 20 million births. For hereditary traits which show continuous variation about the normal, an increased mutation-rate results in increased proportions of the extreme variants on either side of the mean; but if the trait has already been subjected to much selection towards one extreme, as is likely for human intelligence, it is mainly the minus variants which will be increased in number. The maximum dose which the British report considers tolerable from a genetical point of view is 50 r. to the gonads in excess of the natural radiation up to the age of thirty, and this should be received by not more than 1/50 of the total population. The American report recommends that records of the accumulated life-time exposure to radiation should be kept for every individual, that the average exposure of the population's reproductive cells to radiation above the natural background should be limited to 10 r. from conception to age thirty, and that individual persons should not receive a total accumulated gonad dose of more than 50 r. up to age thirty, and not more than 50 r. additional up to age forty.

In the manner of presentation the two documents differ fundamentally. The American report clearly aims at being intelligible to the general public. Full reports with technical details are being prepared and will be published at a later date. Although the various sections differ in the amount of technicalities they contain, they all state unambiguously the relevant facts, conclusions and recommendations. In particular the section on genetics is a model of popular exposition of a difficult and debatable problem. Where differences of opinion between scientists exist, these are stated; but instead of confusing the general reader with controversies, stress is laid on the points of agreement. To make quite sure that the main facts and conclusions reach the widest possible public, these are once more summarized in a brief "Report to the Public". The British report is written in a spirit of scientific humility and caution which may well leave the general reader with a feeling that it would be best not to bother much about a subject on which so little is known. There is nothing in the British report corresponding to the categorical American statements: "Any radiation is genetically undesirable", or "From the genetic point of view, they [the radiations] are all bad". Yet it is likely that the authors of the British report would agree with these statements. For the scientist, especially the geneticist, the report is highly interesting, just because it deals in great detail—partly in the form of thirteen appendixes—with the data, calculations and considerations on which the final conclusions are based. The intelligent and educated general reader who is willing to spend time and effort on understanding the report will no doubt learn very much from it; but it is to be feared that he will be in a minority, and that the general public, including our legislators, will prefer to get its information second-hand from newspaper digests which, based on a document of this nature, can scarcely fail to be one-sided or otherwise misleading, especially as the report gives little guidance for such a purpose. It seems highly desirable that a digest for the public be prepared as soon as possible by the authors of the report.

NEWS and VIEWS

Royal Botanic Gardens, Kew: Sir Edward Salisbury, C.B.E., F.R.S.

Sir Edward Salisbury, who has been director of the Royal Botanic Gardens, Kew, since 1943, is resigning from that post, having reached the age of seventy. To botanists, both in Britain and throughout the world, Sir Edward is well known, not only for his outstanding botanical work (especially on plant form, reproduction and ecology) but also for his splendid books, which include those for the specialist, those for the student and those for the layman. Through these books, Sir Edward has exerted a profound influence on the advancement of botany. For many years he has worked also for the advancement of science in general (but especially the biological sciences) through various societies of which he has been president or vice-president or secretary. For example, he was honorary secretary of the British Ecological Society during 1917–32 and its president in 1928. He has been president also of several other scientific societies.

Sir Edward Salisbury has been one of the pillars of the Royal Society for many years. During 1945–55 he was the biological secretary and was vice-president in 1943 and during 1948–55. In both these capacities his exceptional gift of organization has proved invaluable. This, together with the great advantage he had to offer as an adviser, has made him an outstanding vice-chairman of the Agricultural Improvement Council since 1944, a member of the Scientific Advisory Committee to the Cabinet during 1943–45, vice-president of the Royal Horticultural Society, honorary adviser to the Ministry of Labour, vice-chairman of the Committee on Colonial Agriculture and a member of the Agricultural Research Council. He is also a governor of several leading universities, agricultural and horticultural colleges and institutes. He was president of Section K (Botany) of the British Association in 1937.

All Sir Edward's earlier academic work was done in the University of London. This culminated in the Quain professorship of botany at University College from 1920 until he was appointed director of the Royal Botanic Gardens, Kew, in 1943. To such a man of many parts, honours in the form of honorary degrees and medals, too numerous to mention, came naturally. It is to be hoped that in spite of his resignation from Kew, the great services of Sir Edward to scientific advancement, exposition and training, through at least some of the many organizations which he has so actively and vigorously supported, will be available for a long time to come.

Dr. George Taylor

Dr. George Taylor, who succeeds Sir Edward Salisbury at Kew, is fifty-two years of age; he was born and educated in Scotland. From the George Herriot School, Edinburgh, he went to study at the University of Edinburgh, where he graduated with first-class honours in botany, and afterwards joined the staff of the British Museum (Natural History) in the Botanical Department, of which he became keeper in 1950 upon the retirement of Dr. J. Ramsbottom. Dr. Taylor has published extensively in the field of Phanerogamic taxonomy; but among his special botanical interests may be mentioned the Himalayan poppies, of which a former director of Kew, Sir David Prain, made a special study. Dr. Taylor published a monograph of the genus *Meconopsis* in 1934. He has also paid considerable attention to aquatic phanerogams, especially the Podostemaceae, that remarkable family of plants living on rocks in rushing water and exhibiting a wealth of morphological and ecological problems. He has taken a prominent part in various botanical expeditions, notably to Rhodesia in 1927, to the mountains of tropical East Africa in 1934, and to Tibet and Bhutan in 1938. He is also a keen and able horticulturist, which was recognized by the award to him this year of the Victoria Medal of Honour of the Royal Horticultural Society. Apart from his work at the British Museum, Dr. Taylor has had considerable administrative experience as botanical secretary of the Linnean Society since 1950, and as one of the general secretaries of the British Association since 1951. Dr. Taylor thus brings to his new duties a record of successful pursuit of three aspects intimately associated with his fresh responsibilities.

British Museum (Natural History): Keeper of Botany

The Principal Trustees of the British Museum have appointed Mr. James Edgar Dandy to succeed Dr. George Taylor as keeper of botany. Mr. Dandy was educated at Preston Grammar School and Downing College, Cambridge. He started his botanical career in the Herbarium at the Royal Botanic Gardens, Kew, where he came under the stimulating influence of Dr. John Hutchinson. In 1927 he was appointed assistant keeper in the British Museum (Natural History) and was placed in charge of the Monocotyledons and Gymnosperms. He is a recognized world authority on Monocotyledons; but his interests have not been confined to that group. He is engaged on monographic studies of the Magnoliaceae and several groups of the aquatic Monocotyledons (including the genus *Potamogeton* in collaboration with Dr. George Taylor). He has almost completed a Flora of Antigua and Bermuda and is compiling a list of the plants of the Anglo-Egyptian Sudan. Mr. Dandy has taken a prominent and decisive part in the legalistic realm of plant nomenclature, and is a member of a number of international committees dealing with this subject. So far, his published work has been confined to treatments of genera or families preliminary to more detailed monographic surveys; but, under his editorship, two very important works will shortly appear. These are the Catalogue of the Sloane Herbarium to be published by the Trustees of the British Museum, which contains the most extensive botanical collections of the seventeenth and eighteenth centuries, and a Check List of the British Flora to be sponsored jointly by the British Museum and the Botanical Society of the British Isles.

Nature Conservancy: Dr. E. B. Worthington

Dr. E. B. Worthington, who has recently completed his term of office as secretary-general of the Scientific Council for Africa South of the Sahara, has been appointed as deputy director-general (scientific) of the Nature Conservancy and will take up his duties on September 17. After graduating in zoology from the University of Cambridge, Dr. Worthington was Balfour Student there during 1930–33 and took part in, or was leader of, two expeditions to the great African lakes, making a number of contributions to ichthyology and hydrobiology. At that time, in collaboration with his wife, he wrote a general book on African inland waters. In 1934, while demonstrator in zoology at Cambridge, he became a scientist on Lord Hailey's African Survey and, on its completion in 1937, was appointed the first director of the Freshwater Biological Association, Windermere. For two years at the end of the Second World War, Dr. Worthington was an adviser to the Middle East Supply Centre, conducting a survey of scientific work in the Middle East countries, and then in 1946 he joined what afterwards became the Research Branch of H.M. Overseas Service; he spent some years in East Africa preparing a development plan for Uganda and organizing inter-territorial scientific services. On the formation of the Scientific Council for Africa South of the Sahara in 1950 he was appointed secretary-general, and has spent the past year in writing a book on the contribution of science to the development of Africa. Besides his many papers, Dr. Worthington, who is fifty-one years old, has written a number of books, mainly on African inland waters and fisheries. He thus brings to the Nature Conservancy a varied experience in biological research and in the application of science to the conservation and use of land and water.

Royal Agricultural Society of England Medal : Dr. G. D. H. Bell

THE Royal Agricultural Society's Medal "for research work of outstanding merit carried out in the United Kingdom which has proved, or is likely to prove, of benefit to agriculture" has been awarded to Dr. G. D. H. Bell, director of the Plant Breeding Institute, Cambridge. Bell's success as a plant breeder is not unrelated to his wide knowledge of plant husbandry and his ability to anticipate agricultural developments. In 1943, at the time when autumn-sown cereal crops were gaining favour, he introduced his two-row winter-hardy Pioneer barley, a variety that represented a new departure in malting barleys. Then came the six-row winter type Prefect of reasonably good malting quality. Prefect was followed by Proctor, a barley that combines to a very considerable extent malting quality and responsiveness to intensive cultural treatment. This variety, coming at the time it did, offered at least a partial solution to the mounting conflict between the brewer who looks for malting quality, and the farmer who wants yield and is aware of the potentialities of some modern varieties under liberal manuring. The next of Bell's barleys, Provost, perhaps carries this reconciliation a stage further, for here we have a variety which in malting tests has given a higher average extract than Proctor. Another of his products is the Minerva Maple pea.

While these new varieties represent the more tangible expressions of Bell's contribution to British agriculture, his work on breeding techniques, particularly his investigations in the Triticinae involving the study of interspecific and intergeneric hybrids, their disease reactions and the cytology and fertility of F_1 hybrids and derived amphidiploids, has materially added to the store of information fundamental to future progress. Incidentally, it is work of this kind that emphasizes the futility of attempting to draw a line separating the 'pure' and 'applied' sides of science; indeed, progress demands that research goes hand-in-hand with the application of available knowledge. Dr. Bell has made numerous contributions to the literature of plant breeding, and he is well known to the agricultural reader for his able articles entitled "Crops and Plant Breeding" that are a feature of the *Journal of the Royal Agricultural Society.*

Woods Hole Oceanographic Institution

REAR-ADMIRAL EDWARD H. SMITH has retired from the directorship of the Woods Hole Oceanographic Institution, having reached the age-limit, and has been succeeded by Dr. Columbus O'D. Iselin, senior oceanographer in the Institution and associate professor of physical oceanography in Harvard University. During his six years as director, Admiral Smith has expanded both the shore and ship laboratories and equipment of the Institution and broadened its interests. It was largely due to his efforts that the research vessel *Crawford* was acquired recently for studying the formation of hurricanes (see *Nature,* August 18, p. 349, and July 28, p. 181). His successor, Dr. Iselin, has been with the Institution since its inception in 1930. A former student of Dr. H. B. Bigelow, he started his oceanographical career on an expedition to Labrador in his own schooner *Chance* in 1926. In 1931 he took command of the research vessel *Atlantis* on her first cruise in the North Atlantic after the ship was built in Denmark. Dr. Iselin served as director of the Institution during the Second World War and resigned in 1950 to devote more time to scientific studies. For his work for the United States Navy on the application of science to undersea warfare, he was awarded in 1948 the Legion of Merit. In 1951 he received the Agassiz Medal of the U.S. National Academy of Science.

The Functions of the Press Council

THE broadsheet, "Performance of the Press", recently issued by Political and Economic Planning (22, No. 397; pp. 20; 2*s.* 6*d.*), considers three aspects: current criticisms of the Press; the Press Council and its objects; and the functions of the Council. In considering the first, P E P does not specifically consider the reporting of science, but notes that the tastes and attitudes of readers govern the nature of the Press at least as firmly as the Press moulds the opinions of the public. After reviewing the work of the Press Council during the three years of its existence, P E P points out that the purposes of the Council, as envisaged by the Royal Commission and adopted in the Council's objects, cover three different functions: as an institute; as a trade association; and as a tribunal. It seems clear that the present basis of the Press Council is too narrow to allow it to carry out the institutional aspects of its work satisfactorily. Its aspects as a trade association include such matters as newsprint, recruitment and training, labour relations, and productivity, some of which are already dealt with by other means, and it appears that most members of the Council consider that the Council should not concern itself with these affairs. P E P notes particularly the importance of the training of journalists, suggesting that the whole subject of education, recruitment and training of journalists deserves a study by itself. The Press Council has, however, concentrated its attention on its function as a tribunal, dealing with points of conduct in a quasi-judicial capacity. It has provided a possibility of appeal both for the public and for journalists themselves and must have made many people think twice before leaving the way open for criticism. Nevertheless, P E P considers that the Council may never develop into the kind of body envisaged in the broadsheet or by the Royal Commission unless it extends its activities, and that the next stage should be to strengthen and develop the Council to enable it to carry out all its professed objects effectively.

Duck Stamps

FOLLOWING the great droughts of the early 1930's when farmers in the 'dust bowl' of the United States were panic-stricken and in poverty, the number of waterfowl reached the lowest recorded point in American history. Soon after, the Biological Survey was set up and Government funds were set aside for the purchase and restoration of submarginal and other lands for wild life, with special emphasis on migratory waterfowl. These funds were insufficient for the national need, and the Duck Stamp Act, formally known as the Migratory Bird Hunting Stamp Act, came into being. Its purpose was to supplement and support the Migratory Bird Conservation Act by providing funds for the acquisition of areas for use as migratory-bird sanctuaries, refuges and breeding grounds, for developing and administering such areas, for the protection of certain migratory birds, and for the enforcement of the Migratory Bird Treaty Act. Since 1940 there has been little in the way of congressional appropriations specifically for the acquisition and development of lands for migratory birds, and the Duck Stamp receipts have taken on added importance. From 1935 until 1953, some 8,500,000 dollars of Duck Stamp funds were used for refuge development, and slightly more than 10 million dollars for operational maintenance. A description of the scheme and of some of the refuges which have been purchased are described in Circular 37 of the Fish and Wildlife Service of the United States Department of the Interior.

Elephants and Electric Fences

CONFLICTING views about the deterrent effects of electric fences on elephants are described in a recent issue of *Oryx* (3, No. 5; August 1956). J. A. Hislop has had unfortunate experiences with three fences in Malaya over a period of seven years and, although one fence remained undamaged for about two years, it was then breached in a number of places and was never again effective. Describing his experiences in Malaya before the War, E. O. Shebbeare found that electric fences were quite effective if they were adequately constructed and regularly patrolled. A. H. Fetherstonhaugh, who, until recently, was chief game warden of the Federation of Malaya, states that electric fences were most useful in protecting rubber estates from wild animals; elephants were difficult to deal with because of their size and sagacity but, provided they had sufficient range and adequate fodder and that electric fences were not erected across a major migration route, the fences were quite effective in preventing their passage through restricted territories.

Citrus Research

THE contemporary *Bulletin of the Research Council of Israel* (Sect. D, Botany, 5, No. 2–3; 1956) is devoted to the Fourth International Congress of Mediterranean Citriculture, held in Israel during May 1956. Among the topics discussed, and here set out in detail, were the anatomy and histology of healthy and xyloporosis-affected Palestine sweet-lime rootstocks budded to Shamouti sweet orange; rootstock–scion influences in the morphology and anatomy of the bud union of Shamouti orange; orange leaf transpiration under orchard conditions; *mal secco* of citrus in Israel and neighbouring countries; the effect of different factors on the ascorbic acid content in citrus fruits—the relationship between species and variety and the ascorbic acid content of the juice; an investigation into the process of flower and fruit abscission of the Shamouti orange; studies on the viability of citrus seeds and certain properties of their coats; toxic influences of sodium and sulphate ions on citrus seedlings.

Handbook on the Use of Chemical Weedkillers

DURING the past ten years advances in the use of chemicals for the control of weeds have been so rapid that the subject has become bewildering to the non-specialist. Successful crop production, however, now depends on the intelligent use of these chemicals, and the Recommendations Committee of the British Weed Control Council has done a most useful work in bringing out "Weed Control Handbook 1956" edited by the staff of the Agricultural Research Council Unit for Experimental Agronomy (pp. 130; British Weed Control Council, Cecil Chambers, 86 Strand, London, W.C.2; 1956; 5*s*.). Though intended primarily for the 'adviser', it is full of valuable information for the farmer, research worker or student. After classifying the weedkillers commonly used in Great Britain, Part 1 of the booklet sets out the agricultural and horticultural crops on which they may be safely used and the weeds that may be controlled by each type of chemical. The special problems connected with forest nurseries, lawns, roadside verges and woody weeds are also dealt with. Part 2 provides practical instruction on such matters as spraying procedure, the calculation of application-rates and the decontamination of the sprayer. It also contains chapters on the legal aspects of spraying and on promising new chemicals, and gives the list of approved herbicides for 1955–56 under the Crop Protection Products Approval Scheme. Tables make reference to crop or weed simple and rapid, and a clear distinction is made in the text between firm and tentative recommendations. The Committee hopes to issue a new edition of the handbook every year.

Morgan Crucible Co., Ltd., London (1856–1956)

THE Morgan Crucible Co., Ltd., of Battersea, London, which celebrates its centenary this year, has published in connexion therewith a short history of the firm, written by Richard Bennett (pp. 67+3 plates). As the chairman of the Company, Mr. P. Lindsay, points out in the prologue, Mr. Bennett does not attempt to give a detailed history of its development or to trace all the varied influences that have shaped the growth of a firm in which the tradition of family service has always been strong. The book gives a very readable account of the growth of the firm, and both the text itself and the admirably chosen illustrations relate that growth to the general pattern of industrial activity of the period. There is much in these pages that could well be used as the text for a discourse on initiative and enterprise and welfare in industry.

Grating and Quartz-Prism Polychromators

THE main article in the May issue of the *Hilger Journal* (2, No. 4; 1956) is devoted to a description of two large self-contained polychromators, the first a 3-m. grating instrument which has now been used in industry for several years, and the second a quartz-prism instrument which is announced for the first time. They serve different purposes and are not substitutes for each other. The grating polychromator is the instrument to use for analyses of highly complex alloys, and the quartz polychromator for the analysis of a wide range of alloys with different base metals. Both have four components: a source unit; discharge stand; the polychromator itself, which consists of the dispersing system and the assembly of exit slits and multipliers; and an electronic console which houses circuits for controlling the analysis and interpreting the results. The 3-m. radius concave grating in the grating instrument is ruled by Siegbahn and can be supplied to provide a dispersion of 6 A./mm. or 12 A./mm. in the first-order spectrum. The spectrum range is from about 1940 A. in the ultra-violet to about 8000 A. in the near infra-red, and the instrument takes four minutes to perform a spectrochemical analysis of a substance, printing the result on a strip of paper. The condensing system in the new prism polychromator includes a quartz biprism, and consequently the spectrometer produces two identical spectra which are separated by a long rectangular prism aluminized on two adjacent surfaces and sent to different focal surfaces where they are received by an assembly of exit slits. The quartz polychromator requires no adjustment for temperature and can accommodate thirty-six channels; but the electronic console is built in units so that the polychromator can be built up from a minimum of twelve channels by the addition of units of six.

Units and Systems of Weights and Measures in the United States

THE subject of weights and measures is of wide interest, and many requests for information on both the customary and metric systems of weights and measures are received by the United States National Bureau of Standards from teachers, students and the general public. To serve this need, the Bureau has prepared Circular 570, "Units and Systems of Weights and Measures: Their Origin, Development and Present Status", by Lewis V. Judson (pp. 29. Washington, D.C.: Government Printing Office, 1956; 25 cents), which brings together in a convenient form much of the information that was previously available in separate mimeographed leaflets. The essential differences between the British and United States systems are clearly explained. The origin and early history of units and standards are discussed; with regard to the metric system it is mentioned that, though the use of the system was legalized in the United States by Act of Congress of 1866, it was not obligatory, and at present the Bureau neither advocates nor opposes its compulsory adoption. To satisfy the considerable interest shown in the maintenance and preservation of the United States national standards of length and mass at the Bureau, a special door, fully protected by an alarm system, was installed during 1955 so that during working hours the vault in which the standards are kept can be viewed by those interested. At other times the steel outer doors are locked. The circular concludes with ready-reference conversion tables dealing with lengths, areas, capacities and weights. For scientific workers and industrialists requiring more extensive information, the Bureau has published "Units of Weights and Measures" (Miscellaneous Publication 214).

Catalogue of Optical Glasses

OPTICAL glass has been made at the Smethwick (Birmingham) glassworks of Chance Brothers, Ltd., since 1848, though since 1948 the main production has been concentrated at the war-time 'shadow factory' at St. Helens, Lancashire, formerly used by Umbroc, Ltd. Some melts are still made at the Umbroc Works by the 'classical process'—that is, each pot of glass is cooled slowly to produce as many large lumps as possible for subsequent moulding into slabs; but another method now employed to an increasing extent for the production of colour filter glass in sheet form or of raw material for the production of lens blanks is to roll the molten glass into sheets $\frac{1}{4}$–$\frac{3}{4}$ in. thick. The classical process is also used at the Smethwick works for certain glass types; but, in addition, platinum pots of 12–16 l. capacity are used for melting rare-earth and other special glasses. Full details of the physical properties of the various glass types produced, together with available sizes and batch reproducibilities, are listed in Catalogue O.S.16, which has recently been issued. The glass types are arranged in groups and described as 'crowns' or 'flints' with a generally accepted, but arbitrary, division at $V = 55$ (V represents the reciprocal dispersive power or constringence) for indices (n_d) of refraction in air for the sodium-D line below 1·6, and at $V = 50$ for higher indices. Nine spectral lines are used for determining the optical properties, and routine measurements of the refractive index and dispersions of each production melt are made with a Hilger–Chance precision refractometer.

South Australian Museum, Adelaide: Report for 1954–55

THE annual report of the South Australian Museum for 1954–55 (pp. 11. Adelaide: Government Printer, 1956) records the retirement of the entomologist, Mr. H. Womersley, and his appointment as honorary acarologist. Dr. E. T. Giles has been appointed entomologist, and he reports that a considerable amount of re-organization has been undertaken since his arrival. The apparatus and equipment have been rearranged and the library reclassified to give a more logical sequence. Mr. H. Womersley was in charge of a scientific expedition to New Guinea, where collections of mites, largely consisting of new discoveries, were made and brought back to the Museum. Mr. William A. Cassidy, a Fulbright research student from the University of New Mexico, has spent a considerable time studying the numerous meteorites in the collections of the Museum.

Ciba Foundation, London: Report for 1955

THE annual report for 1955 of the Ciba Foundation for the promotion of International Co-operation in Medical and Chemical Research (pp. 43; from the Foundation, London; 1956) gives details of the five discussion meetings and the four sessions of the quarterly clinical forum held during the year, as well as particulars of the seven international conferences, the proceedings of four of which have been published in book form. The three on ageing in transient tissues, on bone structure and metabolism, and on paper electrophoresis, respectively, were due for publication. Five scientific film sessions were also held during the year, and the seventh annual lecture was given in Stockholm by Prof. H. Olivercrona on "Hypophysectomy in Diabetes". Accommodation was provided at the Foundation for nearly eight hundred visitors from thirty countries who came to London in connexion with their scientific work. Six British medical graduates were granted short-term bursaries for work in France, and the first seven international awards were made for papers descriptive of research relevant to the problems of ageing, a field in which the Foundation is attempting to encourage long-term research by younger workers. Besides particulars of publications of the Foundation, the report includes some notes on the library, which was ready for visitors early in June, and lists of holdings and of periodicals received.

Grants for Education in Plastics Technology

THE Trustees of the Plastics Industry Education Fund have recently announced their plans for the support of education in plastics technology during 1956–57, among which are a number of new projects. In addition to the grants for the seven students at the Borough Polytechnic, London, who last September started a full-time course for two years leading to the diploma of the Plastics Institute, a further £1,000 has been allotted for grants to students living in the London area who wish to take up this course next September. The Birmingham College of Technology is being offered £1,000 to start a 'sandwich' course in plastics technology which will last four years, with the students spending alternately six months at the College and then six months in industry. It is intended that the students should be recruited from school and not be released from industry in order to attend the College. £175 has been granted to Mr. S. H. Heath, a lecturer in plastics technology at the Birmingham College, to enable him to visit firms in Europe for three months and study and report on recent developments in new materials and polymerization processes. Funds have been provided for a research studentship in plastics technology, worth £300 a year for two years, at the Acton Technical College, London. A grant of £500 for the purchase of equipment for teaching plastics technology has been made to the Cardiff College of Technology and Commerce, where a course leading to the diploma of the Plastics Institute was started last September and where it is hoped to establish shortly a course for the associateship. There will again be available from the Fund a sum of £1,000 for training grants to young men or women working in the plastics industry to study full-time for a degree in science or engineering, and this year applications will be considered also for assistance to take a full-time course in industrial design.

Magnetic Resonance: Symposium at Bangor

A SYMPOSIUM on magnetic resonance, arranged by the Liverpool and North Wales Branch of the Institute of Physics, will be held in the University College of North Wales, Bangor, during September 26–27. Lectures will be given by the following: Dr. B. Bleaney (Clarendon Laboratory, Oxford), free atom resonance; Dr. J. G. Powles (Queen Mary College, London), spin echo techniques; Dr. R. E. Richards (Department of Physical Chemistry, Oxford), magnets; and Prof. E. R. Andrew (University College, Bangor), nuclear magnetic resonance work and other research at Bangor. At the symposium consideration will be given to the formation of a group to provide future occasional meetings. Further information can be obtained from Prof. E. R. Andrew, Physics Department, University College of North Wales, Bangor, Caernarvonshire.

Announcements

A. S. P. DA SILVA has been appointed by the Brazilian Ministry of Agriculture to be chief of the Experimental Station at Pelotas.

DR. J. B. M. COPPOCK, director of the British Baking Industries Research Association, Chorleywood, Herts, and Dr. C. R. Jones, of the Research Association of British Flour Millers, Old London Road, St. Albans, Herts, have been appointed corresponding editors for Great Britain of *Cereal Science Today*, the new journal of the American Association of Cereal Chemists. They would be glad to receive news of events or developments of potential interest to readers of the new journal.

THE Oliver Memorial Fund is offering an award of £50 to a British subject for original work or services in connexion with the research, organization or donor aspect of blood transfusion. Applications or information on possible candidates for the award should be sent before September 30 to the Honorary Treasurer of the Fund, c/o National Provincial Bank, Ltd., Holborn Circus, London, E.C.1.

THE Chemical Society is offering grants from its Research Fund for the assistance of research in all branches of chemistry. About £700 a year is available for this purpose, the income being derived from a donation of the Worshipful Company of Goldsmiths, from the Perkin Memorial Fund, and from other sources. Applications for grants should be submitted not later than November 15 to the General Secretary of the Chemical Society at Burlington House, Piccadilly, London, W.1.

THE Committee on Statistics of the University of Chicago is offering a number of post-doctoral awards for study in statistics by persons whose primary field is not statistics but one of the physical, biological, or social sciences to which statistics can be applied. The awards are for the academic year 1957–58 and are worth 3,600–5,000 dollars. Application should be made before February 15, 1957, to the Committee on Statistics, Eckhart Hall, University of Chicago, Chicago 37, Ill.

THE British Society of Rheology will hold a conference on "Extrusion and Rolling Processes" during September 27–28 in the Stephenson Hall of the University of Sheffield. Six papers will be read, covering various aspects of the rheology of metals and of plastics. Further information can be obtained from the Honorary Secretary of the Society at 52 Tavistock Road, Edgware, Middlesex.

THE Iron and Steel Engineers Group of the Iron and Steel Institute will hold a meeting in South Wales during October 4–5. During the mornings, papers will be read in the Grand Pavilion, Porthcawl. In the afternoons, visits will be made to the Margam Works (blast furnaces, coke ovens and sinter plant) and the Abbey Works (open-hearth steel plant and wide strip mills), respectively, of the Steel Company of Wales, Ltd. Application forms, to be completed by September 10, and further information can be obtained from the Secretary of the Institute at 4 Grosvenor Gardens, London, S.W.1.

THE third British Weed Control Conference, organized by the British Weed Control Council, will be held in the Norbreck Hydro, Blackpool, during November 6–8. There will be two general discussions on the first day: one on whether weedkillers are being developed and used for ensuring efficient food production, and the other on wild oats. The subsequent days will be devoted to the reading of research reports. Further information can be obtained from W. A. Williams, British Weed Control Council, Cecil Chambers, 86 Strand, London, W.C.2.

THREE awards have recently been made from the Mental Health Research Fund, as follows: a grant of £200 to Dr. James A. Hislop, of the Department of Human Ecology and University Health Service, Cambridge, for investigation of the length of stay of patients admitted to Fulbourn Hospital from the Isle of Ely during the past hundred years; a Leverhulme grant of £1,000 a year for two years to the University of Leeds towards the cost of a senior research fellowship awarded to Dr. Max Hamilton, senior lecturer in the Department of Psychiatry, for work on the treatment of paranoid disorders by electro-convulsive therapy and insulin shock; and a travelling fellowship of £1,150 to Dr. R. E. Hullin, lecturer in the Department of Biochemistry, University of Leeds, to spend a year in the Department of Physiological Chemistry, University of Pennsylvania, investigating new biochemical methods which may be applied to the study of the blood in manic-depressive psychoses and endogenous depression.

THE ROLE OF SCIENTISTS IN WORLD AFFAIRS

IN August last year the World Association of Parliamentarians for World Government organized an international conference of scientists to consider the dangers to world peace due to the development of nuclear weapons. At this conference three commissions were formed to discuss respectively the destructive potentials of nuclear weapons and the possible consequences of their testing in peace and massive use in war; the technical problems of the supervision and control of the production and use of nuclear weapons in order to enforce their prohibition; and the responsibility of scientists for the direction of their work, the uses to which it is put, and the public knowledge of its implications. A brief report of this conference was published in *Nature* (176, 289; 1955).

At its conference this year, the Association set aside one day for a discussion of the work of these three commissions. Opening the discussion, Dr. J. Bronowski reported that the commissions had been reconstituted as independent bodies of scientists, as it was considered that any conclusions reached would then command more respect than they would if they were associated with a political organization, however eminent it be. Recognition of the commissions by established scientific bodies is being sought, and has already been obtained from the Atomic Scientists' Association. It is intended that eventually, by consultation among interested scientists, agreed statements shall be drawn up and published.

Passing on to consider in more detail the work of the third commission, that on the responsibility of scientists, of which he is the secretary, Dr. Bronowski reported that an interesting exchange of opinions had taken place, but that the members of the commission had not yet got to the stage of drawing up an agreed statement; so at present he could only outline some of his own views. He recalled how the sight of the devastation at Nagasaki had convinced him that it is the duty of scientists to work to bring about a universal understanding of the implications, both for good and for evil, of the development of atomic energy. They have this responsibility not only because of their specialized knowledge but also because they have learned to approach problems in a scientific way. They know full well that the most subtle theory is useless if it cannot stand up in a world of hard facts. It is useless, for example, to talk eloquently about raising living standards throughout the world if there is not even the possibility of making available the energy necessary to do it, as indeed there was not until the first atomic pile was successfully operated in 1942. Thus it is particularly important in political discussions to learn what is practicable and what is not, and to act accordingly. The scientist knows also that the end never justifies the means, or rather that the end cannot be distinguished from the means. The results can never be altered to fit the theory. This professional integrity of the scientist is needed also by those who have to tackle problems concerning the affairs of men.

Reporting on the activities of the second commission, that on the international control of atomic energy, Dr. P. E. Hodgson, its secretary, said that an account of its discussions at the 1955 conference, together with a survey of the main problems to be studied, had been published in the *Atomic Scientists' Journal* (5, 209; 1956). He went on to survey the main developments in the field of international control during the past year. On one hand there have been several encouraging examples of international co-operation on atomic energy, such as the Geneva Conference in 1955 on the Peaceful Uses of Atomic Energy, the European Organization for Nuclear Research (C.E.R.N.), and Euratom; but, on the other hand, the power and efficiency of nuclear weapons have steadily increased. It is now possible for any one of the major atomic Powers to inflict on another, without warning, severe and widespread damage of the most lasting kind. But such a blow would not prevent an equally devastating retaliation. This situation is gradually hardening due to the development of intercontinental rockets, against which there is even less defence possible than against high-altitude aeroplanes. Thus international control is becoming steadily more difficult, though even now it would not be impossible if wide powers of inspection were given to a control agency. Any plan for international control would, however, always have to take into account the possibility of hidden stocks of fissile material that could not be detected by any physical means. The most effective and practicable preliminary steps towards international control are the cessation of tests of nuclear weapons and of long-range rockets.

The work of the first commission is being temporarily suspended in view of the establishment of a United Nations commission with similar terms of reference. It will reconvene to study the report of the United Nations commission when this is published.

In the ensuing discussion, Prof. A. Haddow pointed out that the scientist has no mandate to decide the future of the world. His main duty is to publicize the details of his work, and to educate the public to an understanding of their implications. Then, as a citizen, he takes part in the political debate to decide the applications of scientific knowledge that shall be made. The growing number of contacts between scientists and politicians are greatly facilitating the diffusion of the new knowledge. Finally, he considered that there is a very strong case, on scientific, humane, medical and political grounds, to cease tests of nuclear weapons.

Prof. B. G. Whitmore brought out clearly that the *inter*national control of nuclear weapons is not possible as the nations are organized at present, owing to the possibility of hidden stocks of fissile material. But it may be possible to organize the nations into one body so that a *supra*national control becomes practicable. This was supported by Prof. R. W. Ditchburn, who urged scientists to play their part in the creation of a strong interwoven network of international co-operation.

In his concluding remarks, Dr. Bronowski underlined once more the dual nature of the task of the scientist: to assist in keeping and building peace, on one hand, and in raising living standards on the other. It is in these two key roles that the scientist has a great responsibility to the rest of human society.

P. E. HODGSON

THE WEATHER IN THE ANTARCTIC

IN the recently published Meteorological Office Geophysical Memoir No. 94*, Mr. H. H. Lamb reports on his work as meteorologist aboard the whale factory ship *Balaena* during the antarctic summer of 1946–47. The *Balaena* carried aircraft for spotting whales, and Mr. Lamb's task, so far as immediate operations were concerned, was to forecast weather and swell for the aircraft and the small whale-catching vessels. Broadcast observations were collected to compile once daily a synoptic map of much of the southern hemisphere, which was used in conjunction with local observation for the forecast work. No observations were received from other whaling vessels, and observations south of Australia, South Africa and South America were very scanty. Though meteorological observations have, of course, been taken in antarctic waters by numerous expeditions, it is believed Mr. Lamb operated the first weather-forecast service there.

It was found that knowledge of the structure and movements of pressure systems, air masses and fronts gained in the northern hemisphere was, after experience of the effects associated with the pack ice and topography of the Antarctic Continent had been gained, perfectly applicable in the Antarctic. Although the nearest reporting station was sometimes two thousand miles away, the forecasting work was very successful. Special attention in the forecasting work was paid to the sub-tropical anticyclones, as their positions and intensities largely determined the movements of the main warm-air steering currents of depressions. Care, too, had to be taken to maintain on the charts all fronts which might affect the ships.

The general weather over the Antarctic Ocean was very disturbed, with one depression soon following another and the only sunshine occurring in a break of a few hours in the clouds every three or four days. As the cloud system of one depression moved away, the next could always be seen approaching. For a short period the ship was less than a hundred miles from the Antarctic Continent, and in off-shore winds the sky was sometimes quite clear. In spite of the great amount of cloud and the fact that there was rain or snow on 122 of the 131 days spent in the Antarctic, the precipitation measured was only 43·6 mm. water, equivalent to an annual precipitation of 4 in. a year—a desert value. The value is not to be taken very exactly owing to the difficulty of giving only just enough heating current to the rain-gauge to melt the snow and no more, and also to loss of catch by the disturbance to airflow caused by the ship. Cumulo-nimbus clouds were frequent, and inversions only occurred occasionally.

The mean pressure south of 50° S. was only 982 mb., and the maximum only 1013·4 mb. These values are much lower than over corresponding areas of the northern hemisphere and suggest that there is unequal sharing of air between the hemispheres. Mr. Lamb, using all the available information, gives in the memoir a mean pressure map of the southern hemisphere. This has a weak anticyclonic area over the Antarctic Continent (pressure about 1,000 mb. reduced to mean sea-level), a ring of depressions off the edge of the pack-ice of central pressures about 980 mb., and then a steady rise to the sub-tropical high-pressure belt in 30° S. Daily weather maps show that the south polar anticyclones cannot be regarded as permanent and that the general situation over the Antarctic Continent is sometimes cyclonic.

CONSERVATION OF FISHERIES

A CONFERENCE on fisheries conservation was held in Rome during April 18–May 10, 1955, and was attended by delegates from forty-five countries. The conference was convened by the United Nations Organization in order to assist the International Law Commission in preparing draft articles on basic aspects of international law on fisheries, and a report was presented to the Commission in June 1955. The papers read at the conference have now been published*. They include important general contributions on fisheries resources and regulation by M. Graham, M. B. Schaefer, G. Belloc, W. C. Herrington, J. L. Krask, G. L. Kesteven and S. J. Holt, as well as summaries of actual international conservation problems such as the North Sea fisheries (C. E. Lucas), the Pacific halibut (H. A. Dunlop) and the Fraser River salmon (L. A. Royal). That it should be possible to control and conserve such diverse fishes indicates how much scientific knowledge has advanced in recent years.

Mr. Graham stresses that T. H. Huxley's dictum—let the fisherman be free—should be followed unless there is evidence that fishing activities are seriously influencing the yield of a fishery. He points out that among the effects of over-fishing one must distinguish a decline in total yield from a decline in catch per unit effort or a decline in average size of fish. The latter two effects may not be a sufficient reason for regulating a fishery, although from economic causes (lack of recruitment of boys to the industry, no market for small fish) they may limit it. Dr. Schaefer expounds the whole theory of fishing and the equilibrium catch; and although he mentions the maximum economic catch, it is apparent that he regards the production of the maximum sustainable yield as the main object of conservation. This thesis underlies most North American fishery regulation; but the maximum yield does not seem to have been obtained yet from the Pacific halibut. From Dr. Schaefer's own contribution on the tropical tunas, it would seem that high catches of yellowfin tuna near the limit of sustainable yield during 1948–51 resulted in an economic regulation of the fishery to a lower level in later years. In the North Sea all three effects of over-fishing have been experienced, and the recent international agreement on mesh sizes goes only part of the way to solve the problem.

Other interesting papers deal with the influence of the environment (J. E. Tait), the behaviour of fishes in relation to the environment (M. Fujinaga, J.

Furnestin, R. Muzinič, A. J. C. Jensen, R. Kandler, T. A. Kow, G. Ranson, G. Rollefsen and W. F. Royce), the productivity of the sea and the possibility of acclimatizing certain species in parts of the world outside their present range (L. Zenkevich). Some contributions from the Italian, Japanese and Korean delegations are frankly political and seem out of place in a scientific report. However, they illustrate how important marine-produced proteins may be in the national diet of many countries. To some extent this importance may explain the apparent disregard of the conference report at the meetings of the International Law Commission in May and June this year. It is to be hoped that the reported draft articles on fisheries law, particularly that allowing a State to take unilateral action to regulate fisheries outside normal territorial waters, are being carefully scrutinized by the United Nations General Assembly.

GRANTS FOR DEVELOPMENT AND WELFARE IN THE BRITISH COLONIES

THE schemes made under the Colonial Development and Welfare Acts, covering the period April 1, 1955–March 31, 1956, which are detailed in the latest return*, bring the total commitments for development and welfare schemes under the Acts to £147,681,582, and for research schemes to £14,750,061, of which £27,909,965 and £1,889,486, respectively, are for the year in question. Of this last sum, £819,495 is for agriculture, £332,701 for medicine, £281,182 for social science, £139,281 for locust control, £64,279 for insecticides, £51,620 for products research, £19,241 for economics research, £10,880 for tsetse and trypanosomiasis, £3,510 for fisheries and £14,000 for research fellowships.

Of the actual research schemes, £362,000 is for the Regional Research Centre for Agricultural Research in the Caribbean area, while a supplementary £113,567 goes to the Institute for Social and Economic Research in the West Indies over the period 1956–60. £59,905 is capital expenditure for establishing the Fundamental and Applied Nutrition Units at the University College of the West Indies and £42,570 for the establishment and maintenance during 1955–58 of a Fundamental Nutrition Research Unit there. £25,300 is provided for soil and land-use survey in British Guiana, £21,960 for the maintenance of the Rockefeller Foundation Regional Virus Research Laboratory, Trinidad, and £9,740 for establishing seismic recording stations in the West Indies. In South-East Asia £27,946 is for filariasis research at the Institute for Medical Research, Kuala Lumpur, £19,100 for research in the Federation of Malaya on virus and other diseases transmissible from animals to man, and £13,904 for the appointment of a plant pathologist investigating diseases of manilla hemp in North Borneo.

In West Africa £43,100 is for an agricultural improvement scheme in Gambia and a similar sum for the West African Building Research Institute, £20,000 for the preparation of a social, political and economic history of the Benin, and £11,000 for extending the work of the Termite Research Unit to West Africa. In East Africa £82,329 is for the East African Institute of Social Research, Makerere College, Uganda, during 1956–60, £38,100 for the East African Virus Research Institute, £34,000 for the preparation of a Flora of East Africa; £32,770 goes to the Rhodes–Livingstone Institute, £30,914 to the East African Agriculture and Forestry Research Organization, £22,596 to the East African Veterinary Research Organization, £19,215 for the Desert Locust Survey and £16,619 for economic research at Makerere College. £15,000 was contributed towards the activities of the Commission for Technical Co-operation in Africa South of the Sahara and the Scientific Council for Africa South of the Sahara (a further £30,000 being provided from development and welfare schemes), while grants for general research schemes included £60,350 for research on animal physiology under tropical conditions at the Hannah Dairy Research Institute; £50,200 for the Anti-Locust Research Centre during 1956–57 and a supplementary £40,100 during 1955–56; £40,586 for trachoma research in Jordan; £36,300 for the Colonial Pesticides Research Unit, Porton, during 1956–60, and £18,160 for the Termites Research Unit during 1956–60.

Among the major development and welfare schemes of particular scientific interest are the following: £103,600 for the construction of a new chemistry laboratory in East Africa and a further £107,000 for the construction of Nairobi Technical College; £1,653,370 for the intensification of African agricultural development; £350,000 for survey of the Rufiji River, Tanganyika; £328,875 for the construction of trade schools and a technical institute in Tanganyika, and £451,890 for water development and irrigation in Tanganyika. £1,050,000 is for the construction of permanent buildings for the University College of Rhodesia and Nyasaland, and £48,000 for the development of meteorological services for Central Africa. Of the contribution of £1,748,756 to the development plan for the Northern Region of Nigeria during 1955–56, £274,628 is for agriculture, £117,514 for technical education, £338,243 for medical services and health, £548,168 for rural water supplies, £39,395 for veterinary services, £35,861 for leprosy control and £26,771 for forestry. £1,312,500 has been provided for the development of rural water supplies in the Eastern Region of Nigeria, £536,250 for developing medical and health services; and of £1,204,840 for the development plan of the Western Region of Nigeria during 1955–56, £245,210 is for agriculture, £548,810 for medical services and health, £92,010 for technical education, £43,070 for leprosy control, £33,270 for veterinary services, £24,570 for forestry, and £49,600 for rural water supplies. £115,530 is for the development of medical services and £149,278 for soil conservation in Basutoland, £83,724 for development of surface water supplies in Bechuanaland Protectorate, £113,185 for rural development and soil conservation in Swaziland; £82,000 for agriculture and forestry development in St. Helena; £510,000 for irrigation and domestic water supplies in Mauritius; £80,781 for the construction of a pathology building for the University of Hong Kong; £984,000 for the construction of permanent buildings for the University of Malaya; £50,000 for aerial survey in British Guiana; and £45,000 for construction of a chemical laboratory in Jamaica.

BRITISH ASSOCIATION MEETING AT SHEFFIELD

TWENTIETH-CENTURY MAN AGAINST ANTARCTICA*

ADDRESS BY SIR RAYMOND PRIESTLEY

President of the Association

THE British more than most peoples go in for paradoxes. It is therefore not atypical that the British Association should, once in a while, elect as its President a man who has been away from science for some forty years. After all, even in this technological age, the value and the advancement of science in a democracy both depend to a considerable extent upon a correct appreciation of the importance of science by the layman at large. There was an element of statesmanship in the man who coined the phrase "we must educate our Masters". We cannot afford to fumble over this vital question of education while we exist precariously in a competitive world. Especially is this so when at least one of our rivals is not yet committed to majority rule, but has her policy directed by men who have both the sense to mobilize the wealth of new knowledge technology is placing at man's disposal, and the power to compel the rank and file to use that know-how to the best advantage. So I shall make no apology this week as I wander from Section to Section as—shall we say—a touchstone of intelligibility.

As I stand here in my present predicament, I draw courage from two facts. The British Association is this year undertaking a serious study of how it can best discharge its particular responsibility in the circumstances of to-day, which are as different from those that prevailed when the Association was founded more than a century ago as chalk is from cheese. The Association's functions of integration and dissemination are expressed in its title and set out at greater length in its constitution. To-day they are more important than they ever were before, and the duties involved are much more difficult to perform. The world can no longer afford to wait until an annual convention for the announcement of major discoveries in science. A great apparatus of scientific periodicals has in any event removed the need. Yet the annual parade of science before the people should have its value. At that parade science must wear the abbreviated bathing-costume of the nineteen-fifties rather than the Victorian crinoline, so that the beauty, the challenge and the danger of the truth may be seen by all. This aim can only be achieved to the extent that the scientist can state his results in language that can be appreciated at least by the average educated citizen. An approach towards that ideal is one task that we have given to our Division for the Social and International Relations of Science.

A second task that must follow from this first is to attract endowment sufficient to make our means—adequate enough a hundred years ago when pounds were pounds—equal to the performance of a greater task in a more expensive world. To solve the latter problem we must do two things. We have to make our meetings sufficiently attractive so that our membership taxes the accommodation of the great cities in which we meet. At the same time we must convince industry that we have a task worth doing and are equal to that task. This should not be beyond our powers if we think our first problem through.

My second comfort to-night is the fact that I have chosen for my main theme a subject about which, if I know too little, the great majority of my listeners will, from direct experience at any rate, know less. Antarctica is remote. It has therefore still to a great extent the fascination of the unknown. It is vast. Its area is six million square miles; nearly as large as Europe and Australia together. The greater part of the continent's surface lies between 6,000 and 11,000 ft. above sea-level and is covered with ice several thousand feet thick. The oceans surrounding it teem with life as do no other waters in the world. For half a century whaling man has followed in the explorer's track to farm these seas. The continent these waters surround is practically devoid of life, and this is due primarily to the fact that, over most of it, there is no single month in the whole year in which the mean monthly temperature is above the freezing point of fresh water. This is a salient fact to remember. Low winter temperatures, no matter how severe, are not incompatible with the existence of highly organized life-forms. They are therefore not a serious obstacle to civilized man with his present knowledge. Maximum winter cold is one record the U.S.S.R. can justly claim, though only just, for Canada and the United States are not far behind. Yet in no country is scientific man more firmly installed or more at home than in these three.

The Pre-War Years

The story of the recent history of exploration in Antarctica is a fascinating one. Before 1900 the defences of the continent had been breached by a Norwegian seaman so keen to make a first landing that he pushed aside his superior officer and sprang thigh-deep into icy sea. A year or two later this same Norwegian adventurer, Carstens Borchgrevinck by name—a man of parts if not of punctilio—backed by an English publisher, Sir George Newnes, had spent the first winter on the antarctic continent at Cape Adare and made the first tentative push inland on the Ross Barrier—a trivial but a significant record. Much greater things were to follow soon.

The first fourteen years of the twentieth century have been named, not inappropriately, the heroic age of antarctic exploration. The tale is a fitting element in the surge of geographical discovery that was a feature of the peaceful Victorian and Edwardian reigns when major wars were rare and a steady approach towards an eventual Utopia—at any rate for the European ruling classes—was expected by most thoughtful men. This surge of antarctic discovery opened with a sharpening of international interest and in cordial co-operation. European scientific societies, under royal patronage—more common then than now—conferred politely about spheres of interest. Scientific leaders were chosen, or chose themselves; old tried equipment and methods—the Nansen sledge and cooker; men, dogs and arctic tents—were translated to a new field, and the twentieth-century antarctic race was in full swing.

---

* Presidential address delivered at Sheffield on August 29 and appearing in the September issue of the *Advancement of Science*.

By 1904 the more accessible parts of the antarctic coastline had been the temporary homes—for one or two years—of European teams with a strong element of natural science. These first scientists were fortunate, as we now know, in the location of their headquarters. Biological and geological discovery went on apace, and we gained our first slight knowledge of the physical condition of antarctic ice and atmosphere. In the meantime sledge parties penetrated for many miles along the coast and made the first tentative journeys inland.

The Swedes, under Otto Nordenskjöld, were fortunate in their location and lucky in their bad luck. They lost ship and gear in the polar pack, but were consequently pioneers in living on the antarctic land. They survived with courage and cheerfulness through two difficult years, during which they collected evidence of several former antarctic floras and they afforded a good example of international co-operation by being rescued by an Argentine naval vessel.

Bruce and his Scots left behind them, in Argentine occupation, the first permanent antarctic weather station. This last achievement had results that were to be of some importance when the temper of the world had changed. French, German and Belgian expeditions contributed to this mass assault with notable but unspectacular results. From the international effort there were three important exceptions. Norway and the United States, both of whom had considerable polar experience, were looking towards the arctic at this time. Imperial Russia—as she then was—who, many years before, in Bellingshausen, had produced one outstanding antarctic explorer, had relapsed into her more usual rather introspective mood.

I have left the British effort until last, for while it was, geographically speaking, the most notable of all, it also leads naturally on to the second phase—the quest for the southern pole. This period was the heyday of the polite recognition of national spheres of interest, and in Antarctica we started with a long lead through the chance that James Ross had approached the continent in the season 1840–41 at the place where the land is most deeply breached by the sea. Scott effected a landing as far south as 78°, and no one by ship could do much better even to-day. Being of an energetic race—at any rate in all that appertains to physical exercise and sport—his men took to their legs and penetrated deeply into the continent. Employing archaic sledging methods inherited from the Franklin search in the Arctic, but gradually evolving an efficient sledging technique within these limitations, *Discovery* sledge parties set a pattern that accomplished a great deal but was eventually to cost us the pole and several valuable lives. They learned that scurvy was not a menace confined to arctic travel and long ocean commissions. On the southern journey the mere suggestion that his breakdown from scurvy was a cause of comparative failure produced in an extraordinary man an obsession which was to govern the rest of his life and give a name to Shackleton Base to-day. The curious chance that one of Scott's officers had served with Jackson in Franz Josef Land led to the employment of ponies as draught animals in Antarctica, with further diversion of the British mind from that real polar sledging treasure—the dog.

There followed in the next few years the polar quest. In 1908, Shackleton, to some extent in pursuit of self-respect, made the greatest leap forward towards either pole that any leader ever made. He traversed the Ross Barrier 300 miles from front to rear, and when the mountain ranges curved across his path, struck up the longest valley glacier in the world, and penetrated over the plateau in face of a galling head-wind and below zero temperatures to within ninety-seven sea miles of the pole. It is fair to say that when he turned back—a decision surprisingly discreet to one who knew the man—we knew exactly what the southern pole was likely to be like. The only surprise to Scott and Amundsen three years later was the fact that a ski-stick could be pushed its whole length into soft snow because of the absence of strong wind. Shackleton returned—but only just. Forty-eight hours of fine weather on the Beardmore glacier when the party was on starvation rations and looking for a depot was typical of 'Shackleton's luck' as we knew it in that wonderful year.

Of the Amundsen–Scott race I say little because there is no polar story so well known. Within a month two parties of five men stood at the South Pole. One did not return. The British lost the race and gave their lives because their methods were less than the best. We did most of the approach work to both poles and were beaten at the post because we did not fully understand the value of dogs as transport animals nor how to get the best out of those we used. Other factors contributed to the tragedy; but the stark fact is that, with sledging rations completely devoid of vitamin C, the margin of safety of any man-hauling party to the South Pole from any base on the rim of the continent is too small. Scott committed errors of organization for which he more than atoned by the manner of his death. He should not have changed his parties from two units of four men to one of three and one of five. By doing so he endangered the party going home, who had, without measuring or weighing apparatus, to take exactly three-quarters of the food from dozens of weekly bags. He handicapped his own party psychologically by crowding them in a tent meant for four men and disorganizing a very carefully thought-out routine. He made, in my opinion, a bad mistake in taking with him three officers and one long-service seaman. Seaman Evans was in a thought-tight compartment by himself and was naturally the first to break. The weather was unkind. Only recently an American scientist has pointed out that, of all the years of which a meteorological record has been kept, 1912 was the stormiest on record and the winter of 1912 set in unusually early. Nevertheless, scurvy was, I believe, the decisive factor. Under man-hauling conditions, four months is about as long as men hauling sledges can live on rations completely devoid of vitamin C. Once that period had elapsed, nervous and physical deterioration was bound to set in, sores to refuse to heal, and lassitude to supervene. Scott's southern party did not starve to death.

This about completes the tale of British antarctic exploration before the First World War, so far as positive achievement is concerned. But there are other things to record before we are finished with the pre-war years. Australia launched her first antarctic venture in 1911, and by 1914 Douglas Mawson had proved his status as polar leader, polar scientist and traveller, and had, incidentally, set a record of endurance that will never be surpassed. Losing one member of a three-man sledge party down a crevasse with most of their provisions, he saw another die of exhaustion at his side, and then, alone, staggered along for three weeks, to arrive at his base one day after his ship had left for home. In the autumn of 1913, I was with Prof. David at his Blue Mountain home when the news was flashed across in the first wireless communication ever sent from Antarctica to civilization without relay, in itself a significant milestone in antarctic history. Mawson, staying south a second year, more than doubled his results, which, with the time-lag characteristic of our antarctic scientific memoirs, are still coming hot from the Australian press to-day.

These years also saw the birth in the minds of William Bruce and Ernest Shackleton of a significant idea still unfulfilled—the Transantarctic plan, which belongs more properly to the years of war that were to bring the long Victorian–Edwardian age to its end and profoundly change the temper and outlook of mankind.

What were the dividends that accrued from this first twentieth-century wave, characterized as it was by a rather attractive blend of adventure, science, individual rivalry, and international good manners and good will ? There were quite a few, but from among them I should like to pin-point two. I was once a geologist, so I may be excused if I go to that field for my first example. The most intriguing feature of polar geological research has, unquestionably, been the evidence of past changes of climate so revealed. East Antarctica we saw, and see to-day, as a continental shield that had remained relatively stable through the ages with, piled upon it, horizontal sediments, which are a record of its denudation and the profound changes of level that have occurred as the aeons passed. West Antarctica we think of as a prolongation of Andean folds. Between the two lies the so-called Ross–Weddell Graben. We still cannot be certain, as we were certainly not in 1914, whether or not the severance is complete, though evidence from air survey makes it more probable that Antarctica is one continent than two.

On this continent, in 1914, we knew of *Archaeocyathus*, a common ancestor of sponges and corals, occurring in Cambrian limestone-stunted forms it is true, but still evidence of warmer seas. Coal seams seven feet thick of Permo-Carboniferous to Rhaetic Age were found in the Beacon sandstone that caps the horst that dominates Victoria Land. From the Priestley Glacier came part of a Rhaetic tree containing in its tissue a tiny winged spore. From the upper ranges of the Beardmore Glacier—collected by a disappointed and weakening party, carefully cached a few miles from where they died—came 40 lb. of priceless specimens, including *Glossopteris indica*, type fossil of the Permo-Carboniferous so widely spread in Australia and elsewhere. From the fold-ranges of West Antarctica, Nordenskjöld and Gunnar Anderson collected in succession Jurassic, Cretaceous and Tertiary floras culminating in *Fagus antarctica*, the southern beech. Stranger still, in all our wanderings, no single formation of undoubted glacial origin was found older than late Tertiary Age. This remains the classic problem of antarctic geology ; fit subject for discussion at British Association symposia—a problem that as a very ex-geologist I will not attempt to solve. Perhaps palæo-magnetism may yet provide the missing clue and Wegener be finally justified, or finally set aside.

Pre-First World War exploration paid handsome dividends in a more prosaic field. The Compagnie Argentina de Pesca has just celebrated a jubilee, its fiftieth year of whaling, which makes the first shore-based antarctic whaling station stem from Nordenskjöld and his Swedes. To some extent the name misleads, for to the credit of Norway must go most major technical improvements in whaling, from the basic small fast whale-catching vessel to the harpoon gun. Of the vicissitudes of whaling one gets some idea when it is realized that, in one's Victorian youth, whalebone for ladies' stays was a chief objective, while to-day whalebone is the least valuable portion of the whale, and it and the tail flukes are the only parts discarded. There are rumours to-day, however, that whalebone may come back into use as a raw material for artificial silk.

The First World War

In 1914 antarctic exploration was diminished rather than inhibited by the First World War. That War was not quite global in extent, and, in the first years at least, until unrestricted submarine warfare set in, some of the old polite conventions survived from the days when wars were the affair, in the main, of gentlemen and professional soldiers. Shackleton left for the south in pursuit of his Trans-Antarctic quest after having offered ships and men to the Admiralty and having been told to go ahead. As I have said, his first expedition was a great success—in its way unique. Yet Shackleton never showed himself a greater leader than when he brought crew and shore party safely through this second, completely unsuccessful expedition without the loss of a single man. Crushed in the ice of the Weddell Sea, the *Endurance* was lost with most of her records and practically all her specimens.

The boat voyage from Elephant Island to South Georgia was an epic seldom surpassed in the history of navigation. Shackleton, the sailor, made little of it. Shackleton, no mountaineer, dramatized the scramble across the South Georgia ranges overmuch. Shackleton, the undefeatable, made four attempts in tiny ships to rescue his marooned companions and at last succeeded. Then Shackleton, the versatile, donned army uniform and became a clothing and equipment expert in Murmansk. I served both with Shackleton and Scott and very briefly met Amundsen in mid-career. I believe a colleague hit the nail when he wrote : "As a scientific leader give me Scott ; for swift and efficient polar travel, Amundsen ; but when things are hopeless and there seems no way out, get down on your knees and pray for Shackleton". Shackleton Base for a Trans-Antarctic Expedition is right.

The Inter-War Years

I must be forgiven if I have appeared to stress too much these early years, for in these I played a minor part. For the rest I must hasten, picking out only the salient features as I bring the, to me, fascinating story up to date.

As Europe and America recovered their poise, two trends, both important to antarctic exploration, can be recognized. America awoke to Antarctica and brought to her aid all the resources of modern mechanical science. Shackleton, Scott and Mawson had taken the first halting steps in this direction without success. In 1908 I had my first motor-car ride in McMurdo Sound near 78° S. latitude in an open, Arrol-Johnston car with air-cooled engine and with wheels. For ten miles we did thirty miles an hour on windswept sea ice and then met snow and stopped. Scott's first tractors had little better fate. Mawson's aeroplane crashed in Adelaide in 1911, but journeyed to Antarctica as an alleged air-propelled sledge—and stayed at or near headquarters when there. But in the thirties Byrd used tractors and aeroplanes with success and on the grand scale. He flew to the Pole and back, and in 1937 Ellsworth flew across the continent, landing several times on the way. These were major feats and pointed to a new era to come, in which radio, not an unmixed blessing, but an aid that, once available, could not be ignored, combined with many other mechanical and electrical aids to transform the antarctic scene.

Meanwhile, in West Antarctica, quite different developments of equal interest to the polar specialist were taking place. Even pre-1914 War polar exploration was not really dangerous compared with civilized life. But scurvy was, as I have shown, a major hazard, and winter sledging could be very uncomfortable indeed. I have left winter quarters for cold-weather sledging with a sleeping-bag weighing 12 lb. and returned with the same bag 28 lb. in weight. All the extra weight was frozen breath and sweat that had to be thawed out and warmed before I could sleep. In 1907–12 we were strictly geared to the polar quest. One gallon of oil had to last four men a week, or three men for ten days. Not a drop could be spared from its primary task of preparing hot meals. In 1926 or thereabouts a very remarkable generation of arctic explorers arose in Cambridge. They evolved an efficient technique of living on the land, and, on the sea in kayaks: they 'out-Eskimoed' the Eskimos. Gino Watkins and his colleagues did more than any other factor to rehabilitate British polar exploration in Scandinavian countries, where our reputation had rather slumped through Amundsen's easy and clear-cut victory in the polar quest. In 1934 these men transferred their attention to Antarctica as the British Graham Land Expedition under John Rymill. The menace of scurvy had gone (except under catastrophic circumstances) with the availability of vitamin C in tablet form and the rational use of what meat the Antarctic can provide—which, along the coast, is a great deal. Winter travel had been made comparatively comfortable by doubling the oil ration; a simple but fundamental change from which, however, the early man-hauling pole-seekers were inhibited by the nature of their task. From Rymill's generation, in direct descent, stem the early leaders of the Falkland Islands Dependencies Survey, that present British nursery of dog-sledging technique, admittedly unequalled, in this particular respect, in the antarctic world, though our cousins the Australians are hard on our heels.

The Second World War

In 1939 the Second World War broke out, and for some years the Antarctic was deserted as never before in this century. This War was truly global and total. All civilized conventions went by the board, and in the struggle for survival no holds were barred. German raiders used sub-Antarctic bases as supply depots and bolt-holes in their raids on Allied shipping and the whaling fleets. In 1938 the Reich had sent a catapult ship carrying two flying-boats to Antarctica to stake a claim and spy out the land. The subsequent raids underlined the rather sinister emergence of politics and national ambition as motives in the antarctic exploration field. It was a variant on an old theme. Iceland and Greenland in the tenth century owed their exploration and settlement not least to the fact that Eric the Red and his turbulent fellow Vikings could not bring themselves to refrain from homicide. The difference, after all, is one of scale rather than of type. The raider *Kismet* sank nine ships totalling 57,000 tons, the *Pingouin* sank 136,000 tons of Allied shipping and captured a whaling fleet with 22,000 tons of oil.

In 1939–40, before her entry into the War, the United States staged a major expedition which had the distinction of embracing, for the first time, both East and West Antarctica, bases being established both at Little America and at Marguerite Bay in what we call Graham Land and the Americans Palmer Land, a clash of nomenclature that reflects a controversy a century old. In 1944–45, when the Allies' naval supremacy was re-established and the sea war over, a naval expedition under Commander Marr—who first went south as a sea-scout under Shackleton—was sent to West Antarctica, and the Falkland Islands garrison was strongly reinforced. Landings were made at Deception Island and Port Lockroy and the Melchior Islands. The Falkland Islands Dependencies Survey began to take shape.

A new factor in Antarctica had emerged; Argentina and Chile were looking to the south. Is it unreasonable to infer that, in these fateful years, with a bias towards totalitarianism themselves, they had decided—wrongly—who would win the war, and had determined, not unnaturally, to pick up what they could of the geographical loot that might be lying about when the British Commonwealth and Empire had been destroyed? Argentina, at least, had some claims to succession: though not to usurpation when the elimination of the present occupier did not in fact take place.

The 'Cold-War' Years

When we study the history of antarctic exploration from the end of the Second World War the pattern becomes more complex. There is plainly to be seen the reflexion of the great dilemma that confronts civilization in this era of rapid technological development in the circumstances of 'cold war'. As man's mastery of machines progresses and his movements become more rapid, the Earth, considered in terms of time taken to traverse it, shrinks. This fact makes international organization and international understanding more imperative year by year; an international outlook more essential to the survival of civilized man. At the same time, the course of recent events has encouraged an aggressive nationalism which is rapidly bringing about the dissolution of the old colonial empires and the emergence of new States, inexperienced and prickly, eager to assert their new-gained rights and to enlarge their realms.

This dichotomy is mirrored in the antarctic history of the past ten years. The year 1948, for example, saw the conception of the first truly international antarctic expedition. On the initiative of Norway, the Norwegian–Swedish–British Expedition of 1949–52 was launched with purely scientific objectives. Two years of first-class scientific work was done in amity by a truly international team who emerged from the experience with enhanced mutual respect and a record of work of unsurpassed value. The inland-ice of Queen Maud Land was investigated to a depth of 100 metres by platinum-resistance thermometers and a core taken down to 200 metres. Six hundred and fifty successful radio-sonde ascents were made up to a maximum of 72,000 ft. A seismic profile of the inland-ice was accomplished during a penetration inland of 390 miles. Aeroplanes of the Norwegian and Swedish air forces combined to extend a survey well begun by the expedition's weasel- and dog-sledging parties. Organization was efficient and the work done in comfort, as when my friend G. de Q. Robin lived for several months on the plateau in a caravan fitted up as seismic laboratory and living quarters combined, much as if he were on a vacation tour at home. Yet, even to-day, exploration is not without its risks. Three men lost their lives when their vehicle plunged into the sea over the coastal ice-cliff during a dense fog.

Such amity among the nations, however, remained the exception rather than the rule, for competition is more common than co-operation in the world to-day. In West Antarctica, Britain was faced with claims both by Argentina and Chile, not only to that sector of the continent, but to the off-lying islands and the Falkland Isles as well. By 1945 the South American neutrals had tabled claims to all land to the south of that continent. These claims were based partly on geographical propinquity, partly as successor states to Portugal and Spain—as inheritors of pretensions that stem from the Treaty of Tordesillas in 1494 and the Papal Bull upon which that treaty was based—partly, in the case of Argentina, on occupation for a number of years.

Twisting the lion's tail is to-day a safer occupation than it was a century ago. Yet Britain has reacted vigorously enough, through occupation and administration, upon a major scale. The Falkland Islands Dependencies Survey is a name that stands for an effort in antarctic activity that is, in its way, unique Since 1944 this activity has been maintained on a steadily increasing scale. To-day Britain has ten permanent bases in West Antarctica, with a magistrate and supporting team at each. From those on the mainland the old Watkins–Rymill tradition of dog-sledging has been maintained and improved, journeys totalling thousands of miles having been made.

The bases breed their own dogs and carry out continuous trials of equipment and rations. In fact, an experimental laboratory in methods of polar travel has been in existence there for a dozen years. A very complete meteorological record is kept at all stations for the benefit of the whaling industry, from which, until recently, the costs of occupation were mainly defrayed. At some stations an ionospheric and seismological programme is in full swing. Topographical and geological surveys are major objectives. This year a start has been made on an aerial survey of the whole region in dispute.

Side by side with the British bases, sometimes within a few hundred yards, stand those of Argentina and Chile, manned chiefly by Service personnel. Our Chancellery proposes—theirs refuse—arbitration through the International Court. Formal protests are bandied to and fro. Through it all, with very occasional exceptions when for the moment national fervour outruns good sense, the personnel of the expeditions interchange social visits and afford each other mutual help. Straying Argentine St. Bernards are returned by British scientists; anniversaries are celebrated in common; British invalids are cured by Argentine doctors and vice versa; Argentine beef and champagne prove acceptable exchanges for Scotch whisky and English beer.

What will come of this international rivalry it is impossible to predict world balance of power being so delicately poised. In 1948 the United States made a proposal to seven Governments for a limited kind of condominium control. From time to time one nation or another formally reserves its rights. The suggestion of United Nations control finds increasing favour in many quarters and has been mooted in the British Parliament. In the meantime, the situation is bound to have its effect on polar achievement in many ways, of which I may mention two.

It greatly increases the amount of money, man-power and energy expended upon the opening up of the southern continent. If, for example, the U.S.S.R., however pure her motives, gazes polewards, the United States must perforce take notice too. The strategic value of Antarctica, should world atomic war break out, with the consequent likelihood of the destruction of the Suez and Panama Canals, will stem from the fact that all inter-continental seaborne traffic, and much coastal traffic as well, must then proceed via the Cape of Good Hope and Cape Horn. In the circumstances, from this cause alone, concern with Antarctica, as a possible air or submarine base, is bound to be a preoccupation of any great Power.

Antarctic exploration and exploitation are bound, therefore, to become more and more an affair of Governments rather than, as in the past, of individual adventurers or scientific societies. At the same time, if the experience of the past ten years is any criterion, less and less scientific result will accrue per unit of energy and money expended. Foreign ministries, even more so defence ministries, are very remotely concerned with science for its own sake. This marked failure to work up and publish results is, indeed, the outstanding feature of the antarctic record since the Second World War. This is an aspect of modern antarctic exploration to which the British Association, as other science associations, might well give some heed.

I cannot, within the bounds of a single address, hope to deal with the work of all countries in Antarctica since the War. The Americans have planned and carried through operations almost on a war scale. Admiral Byrd goes south periodically with many ships and thousands of officers and men. In 1946, for example, planes from the deck of an aircraft-carrier, standing off the coast, reconnoitred some 800,000 square miles in a few weeks. Airborne magnetometers were used for the detection of islands completely hidden by land-ice. Icebreakers steamed in a matter of days half-way round Antarctica from the Ross to the Weddell Sea, and, incidentally, pulled out Finn Ronne's party, which had done a unique job of dog–air co-operation with the British under Butler along the Graham Land coast. This American party made history by overwintering two women at their base. In theory a further step in co-operation was achieved when an agreement was signed making photographs and specimens mutually available; but alas, things have not worked out so well in practice as was hoped. Returned antarctic explorers are as human as anyone else. One of the announced motives of the American exercise was the testing of men and equipment in case of the outbreak of 'hot' war.

The contributions of Australia, with the veteran Douglas Mawson as the main driving force, and of France, have been outstanding too. In Kerguelen, France has a sub-antarctic scientific outpost of first-class quality and is preparing airstrips there 3,000 metres and 2,000 metres long. An intriguing side-issue is the attempt to acclimatize "reindeer, mink, sheep, pigs, and ponies". From a base in Adélie Land the French have explored widely along the coast and some distance inland. Australia has permanent stations established at Macquarie Island and at Mawson on the mainland. A spokesman has recently defined her objective as the making of short forays at selected points on the antarctic continent, concentrating on specific scientific problems, which suggests that here, at any rate, the old scientific spirit is still alive.

Whaling

No account of twentieth-century man's relationship to Antarctica would be complete without some reference to the history of the whaling industry. Whatever may happen in the future, so far whales, elephant seals and fur seals are the only tangible assets antarctic exploration has produced.

The first shore-based venture in South Georgia in 1904 employed one catcher and took 195 whales. In 1954–55 nineteen factory ships, three shore stations and 254 whale catchers between them accounted for 37,654 whales and produced 372,956 tons of oil and nearly 80,000 tons of meat products. Until the present spate of Government activity set in, antarctic exploration had, through this single asset, paid for itself over and over again.

The whaling industry has not been without its vicissitudes. The price of oil has fluctuated from £8 10*s*. a ton to £170 a ton, though it is now fairly stable at £75. But operating costs increase steadily and to-day the margin of profit has become very small. The success of whaling, of course, even if prices are remunerative, must depend upon the maintenance of the stock of whales, and this has led to international regulation on a considerable scale. In the early days the industry was carried on from shore stations, all of which were, in those less complicated times, in the undisputed control of Britain. The industry was easily controlled by the issue of licences. In 1925 the situation was transformed by the invention of the floating factory, and the stern slipway followed soon. Up the latter the whales could be hauled by winches and flensed and rendered-down on board, thus doing away with the need for a shore base away from the home country. From now on an entirely different type of control was needed. The League of Nations in 1931 drew up a convention which established the principle of the international regulation of whaling on the high seas. In 1933 most companies agreed to voluntary limitation of catches. Whaling inspectors were appointed to accompany all ships in 1934–35. Complication was caused by the defection of Germany and Japan from the League just before the Second World War; but when the War was over, the International Commission was established in 1946. The catch is now limited to 15,000 blue whale units. Despite protective measures, the blue whale stock has greatly decreased, and there are to-day signs that the fin whale stock, now the mainstay of the industry, is on the decline.

The skill of the whalemen of Norway has been both the strength of, and a danger to, the whaling industry. Something in the nature of a Guild of Whalemen has developed with its accompaniment of a jealously-guarded monopoly of skill. The two chief trends of the half-century have been the improvement of the technique of whaling and the more efficient utilization of the body of the whale. In the former field Norwegians have been supreme, though recently useful innovations such as the electric harpoon—to replace the destructive harpoon-gun—and the echo whale-finder have originated in Britain. Other notable developments have been the use of helicopters for finding whales and the attachment to whale carcases of small wireless transmitters so that catchers fitted with direction-finding apparatus can home on them in any weather conditions. In utilization Britain has, perhaps, taken the lead. To-day almost every part of the whale is used. The main use of whale oil is, of course, the manufacture of margarine and soap; but it is also used as burning oil, for tempering steel, for leather dressing, and in lubricants. Experiments in the production of artificial wool from blubber are under way in Japan. Whale-meat meal is used for feeding cattle, pigs, poultry and silver foxes; small quantities of whalebone for the grooving of sliding doors, for collar studs and stiffeners, for cigarette cases and the backs of hairbrushes. Canned whale-meat is to-day, even in peace time, in some countries a common form of human food. In 1954, 30,000 tons of salted whale-meat was used as food for miners in Japan alone. In 1954–55 these by-products were worth nearly a million pounds.

Whaling springs from exploration; but it has, in its turn, had a profound influence upon exploration. Here again, there has been a curious mixture of effects. Whaling captains, by and large, are, not unnaturally, loth to give away the location of good hunting-grounds. From this natural reticence have sprung many of the contradictions and uncertainties of polar history in the past. This trait must have had its effect upon the controversies about priority of claim that have been so frequent and so bitter. Yet there have been from time to time enlightened owners and skippers who have contributed notably to the unveiling of the southern continent and the islands off its coast. From the nineteenth century Messrs. Enderby Bros., John Biscoe, and Weddell immediately spring to mind. Their names are rightly written large upon antarctic maps. In the present century the firm of Salvesen, Captain Larsen—who died while whaling in the Ross Sea—Lars Christiansen, and Mikhelsen, equally deserve to be remembered as explorers as well as whalers.

Another valuable contribution to the exploration of antarctic seas that springs directly from whaling is the oceanographical research carried out by the Royal Research Ships *Discovery I* and *II*, and now continued by the National Institute of Oceanography. This work was originally financed by the United Kingdom from whaling dues. The *Discovery*'s work is essentially a survey of the antarctic seas and their organic resources. These seas have an exceptional density of marine life, and oceanographical conditions are distributed in a simpler pattern than in most other oceans. For twelve years between the wars R.R.S. *Discovery* covered the southern charts with a complex network of courses, encircling the globe. The scientific results surpass even those of the *Challenger*. By 1938, eighty memoirs by fifty authors filled fourteen volumes. More than 4,000 whales had been marked. Her researches on the breeding and life-cycle, the distribution, migrations, and habits of the whale have been of major importance to the successive bodies responsible for the regulation of the industry. The oceanographic survey has revealed the broad structure and mechanics of the principal water masses and currents and certain basic features of the distribution of the ocean plankton.

The Antarctic To-day

So we come to the present day and to a fresh resurgence of interest which we can really claim has science for its main drive. Twice in the past, during 1882–83 and 1932–33, the scientists of the civilized world have planned an International Polar Year. To-day they plan again, but, as is fitting, on a vastly larger scale, the International Geophysical Year for 1957–58. Although it is intended to cover the whole Earth with chains of stations from pole to pole, the systematic exploration of the physical phenomena in and over Antarctica is a most striking component of the plan. A long-range practical objective has been described as a better understanding of climatic variation and the study of the nature of long-period climatic change. We are apt to forget how much the present pattern of our civilization depends upon the latent heat of ice. If the present ice-sheets of the world melted in a hurry, sea-level would rise somewhere about a hundred feet. This would, among other painful things, bring about the greatest slum clearance the world has ever known. The present long-term tendency to glacier retreat is, however, accompanied by a rise in sea-level of only four inches a century. The rise in the temperature of ocean water that accompanies this climatic change has important repercussions on the fishing industry, upon which the welfare and livelihood of tens of thousands of European families depend. Another question still a matter of controversy is whether continents move, and, if so, at what rate. A fuller knowledge of the ionosphere will help in improving wireless communications, which are now essential to our mode of life. Upper atmospheric studies are important in the future development of high-flying aircraft.

The immediate observations that will be made during 1957–58, chosen because it is a year of nearly sunspot maximum, are, however, concerned with the exact recording of physical phenomena which will appear to the layman as the purest of pure science. Yet Sir Edward Appleton has lately reminded us that history has taught us to regard pure science as the capital of scientific knowledge, capital that has yielded astonishing dividends from time to time.

The world is entering on its latest experiment in a big way. A mere enumeration of the subjects of study is evidence enough of the comprehensive nature of the programme. Meteorology, the study of aurora and airglow, geomagnetism, ionospherics, ozone, cosmic rays, glaciology, solar activity, variation in longitude and latitude, seismology and oceanography, are all embraced. I can even visualize a little geology being done on the side, though most of the people concerned may never handle antarctic rock. The total cost of the plan has been assessed at £100,000,000. No less than forty-five nations have pledged themselves to play their part. In and around Antarctica there will be more than forty stations, of which three will be, respectively, at the geographic pole, the geomagnetic pole, and the Pole of Inaccessibility*. These last will be supplied and maintained entirely by air.

The most spectacular element in the plan is the examination of the upper regions of the atmosphere. Man reaches farther towards space than he has ever done before. It is planned to employ man-made satellites, dispatched by means of three-stage rockets, to a height of 200 miles, there to girdle the Earth in an elliptical path which varies between 200 and 800 miles, in 90 minutes dead. The satellite is expected to stay up days or weeks, before it falls and is consumed, as are millions of the meteorites that enter the atmosphere every day. Large rockets will reach out—their tracks like slender fingers—to several hundred miles above the Earth, carrying heavy loads of recording apparatus. Rockoons, smaller rockets launched from balloons twenty-seven miles up, can carry a lesser load to a height of more than sixty miles. Small rockets may be dispatched from aircraft in flight.

Balloons will be launched trailing a variety of instruments, tracked throughout their course by observers, and eventually parachuting to earth. Automation, a cause of anxiety and unrest here at home, can be seen with more detachment as an essential element of the International Geophysical Year plan. Perhaps it is at its most dramatic in the so-called 'Grasshopper', a small recording device weighing 200 lb. which can be dropped from an aeroplane at any desired spot. As described to me, it automatically opens, rights itself on its six legs in true insect fashion and goes into action. 'It gathers weather information at predetermined intervals, transcribes it automatically into International Morse Code, and transmits it by radio at seventeen words a minute." It works for sixty days and records and transmits surface wind speed and direction, temperature, barometric pressure and humidity. To one who has toiled to and fro between hut and screen, this sounds to be a very desirable development indeed—a distinct advance towards *Utopia Antarctica* and not a matter for grousing at all, even if the substitute job is handyman or cook.

Already the International Geophysical Year has begun to work its transformation of the antarctic scene. Direct American flights from New Zealand to Antarctica have taken place. The Russians are in regular radio touch with Moscow, and plan a supply route direct from the U.S.S.R. by air. The continent is becoming studded with little towns. Icebreakers plough the antarctic seas with internal temperature kept at 75° F.: a fact that reminds me vividly of what I reckoned to be one of the hardships of American life. In this great effort Britain plans to play a worthy part. One major expedition, sponsored by the Royal Society, is already established near 76° S. in the Weddell Sea. The Falkland Island Dependencies Survey bases are being reinforced to help.

Dr. V. Fuchs's trans-Antarctic expedition is a horse of a rather different colour, though it will, as a side-issue, contribute to the plan. He intends to cross the antarctic continent from west to east. It has been said in criticism that the British have been so obsessed with the story of Shackleton and Scott that they cling unduly to outmoded ways. We have, it is true, suffered from too strict adherence to tradition in the past. There is an element of gambling in the present Trans-Antarctic plan. But Fuchs intends to take seismic soundings of the ice depth together with a continuous gravity traverse as he makes his way across. In addition to tractors and aircraft, he will have auxiliary dog transport to examine rock exposures he may meet along the unknown country he has to traverse. Of all the modern equipment, the small electronic device weighing less than one pound by which he can home on his moving column from distances up to twenty-five miles attracts me most. If he is fortunate he may come back with results that will, of their kind, be as valuable as anything his more sedentary competitors can possibly produce. And there is an element of adventure that, for any normal citizen, will definitely add to the fascination this particular venture exerts. Good luck to him. May he and his men so conduct themselves that, if they do fall short of complete success, they will, like Shackleton of *Endurance* fame, come out of the trial with reputation not diminished but enhanced.

---

* The term was first used by Vilhjalmur Stefansson to indicate the point in the Arctic Ocean which was theoretically most difficult of access under the sledging conditions prevailing in his time. As applied to the antarctic continent, it must presumably mean the spot on the inland ice most remote from an attainable base.

The Future

When I left England with Shackleton in 1907, I travelled to Australia in six weeks by sea at a cost of £19 from a London where the four-wheeler horse-cab was still commonplace; where radio was in its infancy and a criminal could still hope to outpace the law by ocean travel. I lived in a world which was, by and large, convinced that mankind was unique and life confined to Earth. The expedition left New Zealand on New Year's Day, 1908, and for all its countrymen knew about what was happening in the next twelve months we might have taken off into space. The first tentative flights were being made in machines heavier than air.

To-day I return to England for the British Association meeting from Australia in the inside of three days at a cost of £300; to find Dr. Fuchs in constant touch with his colleagues in Antarctica; in a world in which a Harvard professor of astronomy has recently asserted in a London Sunday newspaper that life exists on a million worlds. His country proposes to launch an earth satellite as part of its International Geophysical Year programme. American airmen are flying hundreds of tons of stores from New Zealand to Antarctica as an ordinary Service transport operation.

Who can predict what may happen in a similar tale of years in the future? Antarctica may be colonized: man may have landed on the moon. On the other hand, it is as likely that, if man's passions get out of hand—and control of emotions is not a notable twentieth-century trait—the survivors of mankind may be plunged in a Dark Age such as has succeeded civilizations of the past at least nine times in the chequered history of mankind. Man is indeed at a crossroads to-day. We of the British Association may well ask ourselves what we can do to help the world to make the choice that will ensure the survival and further progress of humanity perhaps to the point when man is no longer earth-bound.

So far as the future of Antarctica is concerned, we still have too little to go upon for speculation to cut much ice. Now that atomic energy is available and atomic power is immediately ahead, the mere strategic threat of a monopoly of Antarctica by any one Power should by itself suffice to keep the interest of the nations alive. Great and valuable mineral deposits there must be in any continent of this size and kind, though nothing of significance has so far been found. Prospecting on the continental scale, let alone exploitation, will be so costly that, apart from a stroke of luck, it will require finance and organization at least on the national scale to ensure success. In 1951 the two hundred million pound Kitimat project was started in a completely undeveloped area in British Columbia and is just about to pay off. But this is based on cheap local power and will be used for processing aluminium ore brought 4,500 miles from Jamaica. In Antarctica something on this scale would be the least that would be required should large and valuable ore bodies be found. Airborne magnetometers and stereoscopic-camera mapping are already in use in antarctic surveying. Future exploitation lies with the co-ordinated use of airborne surveyors carrying out wide sweeps and of helicopter-borne ground parties equipped for high-speed core drilling and rock sampling. In Canada five geologists with two helicopters have prospected in one season some 67,000 square miles. Attention must needs be concentrated, as at present, on the relatively few exposed rock surfaces where mining could be carried out without difficulties arising from ice movements. Once the ore is located the whole enterprise could gradually go underground. Tunnel or adit entry might be followed by the construction of underground engine-rooms, hoisting gear and mineral dressing plants. Floating power-stations that could be withdrawn for maintenance during the 'closed' season might be a useful expedient in the initial stages; but land-based stations would be essential to any permanent settlement. Once a footing had been obtained, anything might happen in these days of technological man.

It has been suggested, for example, that the Antarctic might have a future use as a vermin-free store for the world's periodical food surpluses, where these might be preserved against the needs of future generations, since widespread crop failures might otherwise spell disaster to a world whose population seems destined to increase. Again, one of the main claims for atomic power is that it can be maintained for long periods in remote places with a minimum of attention and thus might be used for the development of the desert areas of the world, uninhabited to-day because they are too cold, too hot, or too dry. If atomic-powered icebreakers can be built, why not atomic-powered settlements on the antarctic mainland? The harnessing of the antarctic gales is another possible source of power. But everything will depend upon the discovery of a worth-while economic objective, and this is not at the moment in sight. The chances are that, for the remainder of this century, Antarctica will remain the scene of investigations in pure rather than applied science. But man may yet find a way to overcome the latent heat of ice and add a seventh habitable continent to the six he already has in thrall.

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

PHYSICS AND TECHNOLOGY

IN his presidential address to Section A (Mathematics and Physics), Sir George Thomson stresses the need for more young people to be trained in physics and mathematics, since these branches of science are becoming increasingly important in technology. Advances are being made within existing technologies by using devices based on physics and on methods depending on mathematical, especially statistical, analysis, and fresh branches of technology are arising which depend on new scientific discoveries. In industry to-day there are both engineers and physicists, and the number of physicists is increasing exponentially. The value of the physicist to the industrialist lies in the fact that he is prepared to look at things from first principles, to try a variety of quite different modes of attack and to get the thing to work somehow, though the product he makes is likely to be scrappy and to go wrong. The engineer uses his background of experience of design to tidy this product up and to make something which can be used by the ordinary person.

In the early days, technology owed little to science—the smelting of metals, for example, was discovered before science existed. Physics, too, arose largely from curiosity—the study of odd phenomena like the reflexion of one's face in a pool or the attraction of rubbed amber for pieces of chaff. Nevertheless. there was always some interplay between technology and science, as witness the impetus given to the study of heat by the invention of the steam engine. But the real influence of physics on technology started with the advent of electricity. From Faraday came the dynamo; from Maxwell and Hertz radio; and from J. J. Thomson the television tube; and in many of our newer industries based on physical processes the physicist is still the one in charge. Technology thus owes a considerable debt to physics; but this debt has largely been repaid, for without the many machines and devices, such as the mechanical vacuum pump and the innumerable electronic components which technology has developed, progress in physics would have been impossible.

Four particular applications of physics are singled out by Sir George for discussion: the peaceful uses of nuclear energy; the electronic computer; the transistor; and the earth-satellite to be launched by the United States during 1957. First in importance in the peaceful applications of nuclear energy is the production of electricity. Nuclear energy, at present, can be applied only in the form of heat. The reactor, in which the chain reaction takes place by which the uranium or plutonium atoms are split with the release of enormous amounts of heat, is essentially a furnace the heat from which must be transformed by some conventional method into electricity. In the Calder Hall piles, for example, the heat is removed by carbon dioxide gas, transferred through heat exchangers to water and steam, and the steam goes into turbines which drive the dynamos generating the electricity to be fed into the national grid system. In accordance with the programme for the development of nuclear energy in Britain, it is expected that, by 1975, 40 per cent of the, by then, considerably increased generation of electricity in Great Britain will come from nuclear power, thus saving approximately 40 million tons of coal per annum. Only a small part of the cost of the new power will be represented by the uranium fuel, and it is considered that there need be no fears about the possible future shortage of fissile material, whether this be natural uranium or obtained from thorium in a breeder reactor. Sir George forecasts that in the not very distant future electrical energy will be derived directly from the thermonuclear reaction between deuterium nuclei (the basis of the hydrogen bomb), thus eliminating the inefficient heat engine which must occur in the uranium system.

The chief limitation to the wide application of nuclear power is the cumbrous, though essential, radiation shield. This may rule out the nuclear-powered motor-car and possibly also the nuclear-powered aeroplane, since for an Atlantic crossing the saving in weight of fuel through using nuclear power would be balanced by the added weight of the necessary biological shield.

Turning to the use of radioisotopes, Sir George cites two examples, one from medicine of the use of sodium-24 to determine the rate of flow of blood, and the other from engineering of the measure of wear of a bearing.

The electronic computer, because of its versatility and wide range of application in science, medicine and commerce, is considered by Sir George to be comparable in importance to nuclear energy. Its importance arises from, first, its power of discrimination, that is, its ability to influence itself by what itself has found, and second, its speed and the consequent large number of operations it can perform in a given time. The transistor is a device consisting of a minute slice of germanium or silicon, replacing in many cases the thermionic valve, with the added advantage of great reduction in size and probably cost of electronic equipment. It was the result of research in pure physics.

The proposed earth-satellite is regarded by Sir George as an admirable example of the interplay of physics and technology. Its immediate purpose is to make measurements outside the Earth's atmosphere; but it is hoped that it will lead to the overcoming of gravity so that men may travel to other planets. The spherical satellite, some 20 lb. in weight, will be launched by a three-stage rocket and move at a height of 300 miles around the Earth at a speed of nearly 18,000 miles per hour, where it should stay for several weeks sending out continuous messages of the measurements it is taking.

STEEL-MAKING SINCE BESSEMER

SIR CHARLES GOODEVE'S presidential address to Section B (Chemistry) discusses the chain of chemical development which was started by Bessemer, namely, the making of steel by pneumatic processes. The problem to-day is the same as that faced by Bessemer: the preferential deoxidation of the iron oxides in ore with the minimum of other elements, followed by the preferential oxidation under different conditions of the other elements in the impure metal. The usual deoxidizing element is carbon in the form of coke which reduces the ore in the blast furnace. It is not, however, possible to stop the process at the right place, and the pig iron is over-deoxidized and contains a large amount of carbon.

Before Bessemer, the oxidation was done in the puddling furnace which produced 'wrought' iron. Great skill was needed and the process was slow and arduous, requiring two or three hours to produce a quarter of a ton of metal. The open-hearth furnace, invented shortly after Bessemer's converter, operates similarly to the puddling furnace; but the chemical reaction is faster because the temperature is higher, and the evolution of carbon monoxide stirs the bath. A modern open-hearth furnace produces a ton of steel every three minutes.

Bessemer oxidized by blowing air through the metal. The speed of this process is limited only by the danger of blowing the iron out of the converter. A modern converter can make 8 tons of steel in 3 min. and is about a thousand times faster than a puddling furnace.

We now know that at steel-making temperatures a reasonable proportion of the colliding molecules have the required energy of activation to produce chemical change, and the rate of reaction is governed by the rate at which collisions between the right kind of molecules occur. This in turn depends on the rate of diffusion and rate of mixing.

Bessemer realized the importance of mixing; but the explanation of his failure to remove phosphorus was not known in his time. Sidney Gilchrist Thomas found the solution twenty years later: that while it is not possible to burn the phosphorus out of the iron, it can be drawn out under oxidizing conditions by means of a slag formed from strongly basic materials such as lime and magnesia.

In recent years much research has been done which explains quantitatively the complicated selectivity rates governing oxidation and deoxidation. Sir Charles then describes the theory of chemical potential and its application to the removal of phosphorus from iron in a basic converter.

Bessemer steel, however, contains two or three times as much nitrogen as open-hearth steel, and this spoils it for some purposes. The open-hearth also has the advantages that it can use steel scrap as well as pig iron, and it can use pig iron with a greater variety of composition. Hence it has steadily replaced the converter, which now produces less than 15 per cent of the world's steel. The decline of the converter process is now being arrested mainly through the development of large-scale production of oxygen, which can be used, diluted with air, steam, or carbon dioxide, for blowing converters. Oxygen removes most of the disadvantages from the Bessemer process. It reduces the nitrogen content of the steel and makes it possible to melt scrap.

Another pneumatic process has been developed in Austria for making steel by blowing a jet of oxygen down on to the surface of the metal. This impact stirs the metal sufficiently to set up vigorous chemical reaction. More interesting is the fact that the phosphorus comes out before, or along with, the carbon, showing departures from equilibrium conditions by factors of ten to one thousand. This is because the kinetics of the phosphorus reaction are much more favourable than those of the carbon reaction.

Sir Charles concludes by reviewing the future of pneumatic processes. Steel-making still depends on the production of the iron–carbon alloy, pig iron, which is not only off the direct route from ore to steel, but also is costly to make. Steel-makers for many generations have longed to develop a cheap process for converting ore directly to low-carbon steel. Several exist, but they have severe limitations.

The speed of Bessemer's process depends on the dispersion of bubbles of air in a liquid metal. Similar speed could be obtained by reversing the system and dispersing small drops of liquid ore in a hot reducing gas. The British Iron and Steel Research Association is now developing such a process under the name 'cyclosteel'. This is still in its very early stages: formidable technical obstacles stand in its way; but such a method of making steel from powdered ore and coal is extremely attractive.

THE PRESENTATION OF GEOLOGICAL INFORMATION IN MAPS

A GEOLOGICAL map, Dr. T. Robertson points out in his presidential address to Section C (Geology), is a combined lithological, stratigraphical and structural representation of what is known or deduced about the rocks in a region or area of the Earth's surface, the terms lithological, stratigraphical and structural being used in their very broadest sense. Such a map has two functions—one scientific, the other economic. In its primary or scientific aspect, the map is a record of research into the geological history of the region, telling as fully and as lucidly as its limitations permit the story of what has happened to the region during the continuous succession of geographies that it has experienced over a period amounting in some cases, where the pre-Cambrian rocks are known, to some thousands of millions of years. A land surface is generally, however, a destroyer of the Earth's historical documents, not a preserver of them, and few regions possess a continuous series of geographical records even for one set of rocks. It is nevertheless vital in research to bear in mind that, no matter how much of the record is now missing, the geological life-history of the region is one and indivisible, each geographical expression taking from and adding to our knowledge of those preceding it. In its economic aspect the geological map is a means of providing as many geological facts and deductions as can conveniently be given in codified form, with the hope that they will be useful to anyone who is in search of information for economic purposes.

The geological map is in essence a record of deductions from facts rather than a record of facts in themselves. The deductions are partly derived directly from the local evidence and partly indirectly, as by the application of reasoning or analogy based upon what is known, or what is thought, to have taken place elsewhere. It is in these processes, carried on throughout the progress of the survey, that the alternating inductive–deductive flux characteristic of scientific research is clearly shown, and the completed map becomes a record of the results of such research. No geological map, however, is a complete scientific study in itself, for it is a representation of a combined lithological and structural conception based upon the scientific judgment of the surveyor, and this conception cannot be fully explained within the limits set by cartographic means of expression. Hence arises the need for a written explanatory account. The result of the geological survey of an area is a complex of interwoven research items leading to theoretical and practical deductions which have application not only in that area but also throughout the whole range of the science.

The deductions that give rise to the actual texture of the map are affected by two important factors, namely, the type and degree of accuracy of the geological data used and the extent to which deductive processes have been applied to them. Consideration of these leads to the conclusion that the geologist must be his own cartographer, and a plea is entered for greater recognition of cartography as being an essential part of geological research, not a mere tool in the hand of the geologist.

SOME IMPLICATIONS OF THE STUDY OF ANIMAL BEHAVIOUR

IN his presidential address to Section D (Zoology), Dr. W. H. Thorpe remarks that it is instructive to consider in what way developments in the study of animal behaviour since Lloyd Morgan's day have affected our views of the animal, and what are their implications. For Lloyd Morgan achieved a general attitude towards animal behaviour and experiment thereon which is striking for its sanity and balance.

Lloyd Morgan assumed three levels of mind (regarding the instinctive as a level of mind and not only of bodily behaviour). He says: "Bottom level minds, if such there be, are percipient only, having sense awareness and no more. Middle level minds are perceptive and percipient, while top level minds are reflective, perceptive and percipient". These three levels he regarded as associated respectively with the sub-conscious, conscious and self-conscious; although we should hesitate now to use these terms.

The main theoretical innovations since Lloyd Morgan's time are undoubtedly those concerning appetitive behaviour, consummatory acts and releasers.

While the idea of a relatively rigid consummatory act is sound, and the separation between appetitive behaviour and consummatory act probably continues to be as useful as it ever was, recent researches have made it clear that the distinction is not hard and fast, so that the characteristic instances of flexible appetitive behaviour and rigid consummatory act can now better be regarded as the two ends of a series.

Thus recent experiments on the following-response of young birds such as moorhens and coots have shown that the active maintenance of a certain spatial relation to a chosen object turns out to be its own reward. Similarly, with the vocally imitative birds, the very act of imitating, the very fact of achieving the appetitive behaviour, seems itself to be the consummatory act.

Again, naturalists of fifty years ago were impressed by the complexity of the action patterns of instincts. But they had scarcely realized that the innate *perceptual* organization must be no less complex, and they had no idea of the sensitivity and fineness of adjustment characteristic of many organs of special sense, as now revealed by sensory physiologists and ethologists studying the orientation mechanisms of insects and birds.

Such discoveries have led to another modification, namely, the tendency to modify the concept of consummatory act by the concept of consummatory stimuli or situations. Besides 'seeking' to discharge its fixed action patterns and so relieve the instinctive 'tension' accumulating around the mechanism of the consummatory act, there is now evidence that some of the appetitive 'searching' is an attempt to find a key environmental situation. Perhaps there is also some real though very limited purposiveness in the search for a satisfying situation. Actions are not always brought to cessation by exhaustion of internal drives or by cessation of the eliciting stimulus. There are external situations which instead of, or in addition to, acting as releasers for the next phase of behaviour serve to bring the previous phase to a close. In this case they must be effective in stopping a piece of behaviour even when the original eliciting stimulus is still present. They are thus 'consummatory stimuli' or situations, and thus the 'goal' is not always the performance of an action: it may sometimes be the perception of an environmental situation.

Many such modern developments in ethology show a tendency to return to the Lloyd Morgan position at a newer level, consonant of course with the immense development in our understanding of the physiological basis of behaviour. For example, it seems inescapable that much modern work on animal behaviour implies that the vast majority of metazoan animals are perceptive. Moreover, in many highly organized perceptions, the perception of relations involved implies something more than this, which Lloyd Morgan would have taken to be self-consciousness; and a great deal of modern evidence for insight—learning, imitation, play, number sense and reminiscence—gives reasons for considering animals to be reflective in his sense. Modern developments in the study of the higher learning faculties of animals have also served to emphasize the necessity for getting back to the idea of a carefully thought-out combination of objective and subjective approach, exemplified by Lloyd Morgan. The best instruments can be misused, and it is possible to cut our throats with Occam's Razor and to disintegrate our animals with a blast from Lloyd Morgan's Canon. If we try too rigidly to be objective, we may fail to see important features of animal behaviour which become clear to us when we attempt to put ourselves in the animal's place; while to go to the other extreme and be too subjective is fatal. We must safeguard ourselves always with all the knowledge we have of the animal's nervous, sensory and behavioural capabilities and its endocrine equipment. A proper balance of subjective and objective is thus necessary both for a worthy ethology and a worthy psychology.

The result of this recent work on instinctive behaviour and the percipient learning abilities of animals is that some apparent lines of demarcation between man and animal nature have become blurred. Behaviour study seems to be reinforcing physiology in stressing the basic unity of the living system in more and more of its manifestations. Some of the fundamental thought-processes of animals seem far less dissimilar from ours than we once thought, and we now see that even the bees have a propositional 'language'.

Ethology has as yet little to say on the fundamental issue of the relationship between living and non-living states; but it does make an impressive contribution to the chorus of voices which are emphasizing the essential unity of living things and the similarity, in much that is fundamental, between animals and man. But while this is true, it would be a view of the utmost *naiveté* to assume that studies of animal behaviour imply any decrease in the stature of man. For it is sound scientific common sense to see that, if only because of the existence of science itself, man displays emergent qualities far transcending those of the organisms most closely related to him.

THE USE AND MISUSE OF CLIMATIC RESOURCES

PROF. A. AUSTIN MILLER, in his presidential address to Section E (Geography), emphasizes that the climate of a country is one of its natural resources and may be regarded as an annual income of rain, warmth, energy, etc., the conservation and expenditure of which should be systematically planned. The first step in such planning is a full and fair assessment of the available resources; but although voluminous climatic records are available, there are still extensive areas where they are inadequate. Moreover, the data are not always of the most useful kind; more information is needed on evaporation, river flow, actual insolation, soil temperatures and micro-climate, not normally included in the duties of meteorological observers. This emphasizes the need for team-work and co-operation between scientists in many fields—climatologists, geographers, hydrologists, engineers, agriculturists, pestologists, physicists, etc.

The total available revenue of climatic resources is reliable within broad limits over a full year; but the incidence varies diurnally, seasonally and, to some extent, capriciously with the weather. Studies of seasonal distribution and of variability are therefore indispensable, especially in regions of subsistence agriculture, where the population lives from hand to mouth. But the vulnerability of primitive agricultural systems is being reduced by scientific research. Knowledge of the nature and the degree of dependence of crops and stock on climate is rapidly improving in precision; with this knowledge and a full assessment of climate, it is possible to fit the crops to existing conditions and to attain higher yields, better quality, more efficient distribution and, above all, greater security. This applies throughout the world—not just to areas of backward and subsistence agriculture but even to the most advanced and intensive types of commercial horticulture. Much more widely than is generally recognized, supplemental irrigation is needed to obtain increased yields, especially of grass and vegetables.

In more advanced societies with industrial and urban characteristics, and greater technical resources, climatic planning involves: (1) redistribution in space, that is, transfer of water, power, etc.; (2) regulation of consumption in accordance with expectable climatic conditions, banking the surplus heat or rain of one season against the deficiency of the cold or dry season to come. Heat, derived initially from the Sun, is stored in the ground and in water bodies and can be extracted from them as required, magnified by the heat pump and used for domestic heating, refrigeration or even as a source of power. Water is stored in lakes or reservoirs at the surface or in water-bearing strata (aquefers) underground.

Despite an apparently generous rainfall, Britain (and many other industrialized countries) is in immediate danger of water shortage, mainly because of the rapidly growing demand for industrial purposes and the extension of piped supplies to an increasingly urbanized population. Water, from the mains, is now regarded as universally available; industry and settlement are no longer tied to natural supplies; on the contrary, the new industries and new towns, their sites selected for some other reason, demand and determine the water supply (piped). Four possibilities for remedying the resulting threatened shortage are being investigated: (1) extension of surface storage, together with means of checking evaporation losses, which are considerable in summer and enormous in hot climates; (2) transport by pipe-line from areas of surplus (the highland zone) to areas of deficiency and increasing demand (the lowland zone); (3) the re-charge of aquefers, such as the chalk under the London Basin, now being depleted by over-pumping; and (4) the re-use of effluents and other unpurified supplies for industrial and irrigation purposes for which potability is unnecessary.

The world map of power resources is undergoing a revolutionary change and some of the future supplies are climatically determined. Water-power, dependent on relief and climate, is already established; solar energy and wind-power are on the verge of entry into the list of geographical factors. But advances in the technique of transport of fluids (oil and water) by pipe-line and of power and heat (as electricity) by cable diminish the importance of the actual location of supplies and widen the geographical range of practicable utilization of climatic resources. Taken in conjunction with the new assessment of agricultural productivity and the discovery of new uses for hitherto neglected climatic assets, these developments hold out a whole new set of possibilities the potential effects of which are worthy of the close attention of geographers.

PRICE—AND COMPETITION—IN TRANSPORT AS AN INSTRUMENT OF POLICY

THE price of freight transport forms the subject of the presidential address by Prof. Gilbert Walker to Section F (Economics). Railway rates have so far been controlled by the close regulation of a supposed monopoly. For the future (as long, at least, as the Transport Act of 1953, now to be amended by the Transport (Disposal of Road Haulage Property) Bill, shall be effective) transport charges are to be determined by competition between carriers.

Price as an instrument for distributing scarce resources has much to recommend it. Its efficiency can be (and is in an appendix to the address) illustrated by the example of parking. Competition in transport, though active, is certainly not free. There is, by law, only the one carrier by rail.

Road hauliers are limited by law to successful applicants for a licence. The cost of transport does not necessarily reflect the amount of resources consumed by the respective services. The Transport Tribunal has recently heard the case of the British Transport Commission for a schedule of maximum charges to be applied subject to Clause 20 of the Transport Act of 1953. The Herbert Committee, reporting on electricity supply, has declared that the managers of nationalized industries should not take it upon themselves to furnish some facilities at less than cost if this is done at the expense of their better-paying customers. The small road hauliers cannot serve the public except on terms which pay, so what will happen to those traders and travellers who demand facilities which do not cover the direct costs of operation to the carrier affording them ?

The British Transport Commission is proposing to invest £1,200,000,000 in modernizing its plant. More is to be spent on the highways of Britain. There is no organization the duty of which it is to examine and compare the returns to these two quantities. No reduction in the price of carriage by road need be looked for from a programme of road improvement even although costs might be lower, unless the supply of vehicles plying for hire and reward can be increased. The conditions on which the licence to carry by road is being issued by the licensing authorities, first established for passengers by the Road Traffic Act of 1930 and by the Road and Rail Traffic Act 1933 for goods, is recommended as a subject requiring the most careful attention now that competition is to be relied upon as the instrument of policy.

OIL AND INDUSTRY

THE presidential address of Mr. A. C. Hartley to Section G (Engineering), entitled "Oil and Industry", traces the vital parts which civil, mechanical, electrical and other phases of the engineering profession have played in evolution of this industry since Drake drilled his first oil well in Pennsylvania in 1859 up to the present day. In oil exploration, the civil engineer is concerned with surveying, road-building, providing means of access, and subsistence, all contributory to geological and geophysical prospecting. In oil-well drilling, the mechanical engineer, and in oil production, the chemical engineer, both contribute substantially to modern methods of winning crude petroleum. Transportation both of crude oil and refined products again concerns mechanical (pipe-line) engineers, and Mr. Hartley stresses the great opportunities still open to them "to develop and improve plant and techniques and so enable the rapidly increasing quantities of oil required to be transported". Oil-loading in sea-going tankers is another phase of the petroleum engineers' activities, which, with a rise from pre-war 16,000 tons to present-day 32,000 tons capacity of tankers, has brought about not only re-designing of these oil-ships, but also construction of deep-sea jetties for accommodation of multiple tankers of heavy tonnage as well as cargo vessels ; the case of the Kuwait Oil Co., with its 4,200-ft. jetty out to sea, exemplifies present-day trends. Oil distribution concerns pipe-lines, road or rail tank cars, barges for coastwise traffic ; many of the specialized engineering professions are concerned in this.

Mr. Hartley includes some reasoned comments on the growth of the industry during the past sixty years ; discussing the present and future position of the oil industry, he considers that, while it is likely that atomic energy will be developed in Great Britain as rapidly as anywhere else in the world, by 1975 that energy will only be equivalent to about 40 million tons of coal. From this it is concluded that it is unlikely that atomic energy will contribute as high a percentage as hydro-electricity is now doing. Thus the petroleum industry has a long way to go to meet the steeply rising demands of oil consumers, anticipated to be about 70 per cent on last year's (1955) consumption making 1,200 million gallons in ten years time and increasing to at least 1,600 million gallons in 1975. World oil reserves are discussed, and we may expect "the ultimate recoverable quantities of oil in the ground to be sufficient to enable the increasing demands of world economy to be met until it moves into the age of atomic power". A section on 'oil in war' is a brief survey of what petroleum engineers and others accomplished during the Second World War to enable our Fighting Services to maintain superiority. The oil industry has still a vast effort to make and a long future before it, if only "to take over so much of the percentage now being filled by the coal and gas industries until nuclear power brings relief".

The vital part that oil has played in past years in the life of Britain is nothing less than transformation of the whole industrial life of the nation. When it is considered that 4½ million vehicles for carriage of passengers and goods in Britain alone depend on petrol or diesel oil; aeroplanes, naval and most merchant ships rely on it as fuel ; heavy industries require substantial quantities of oil fuel ; lubricating oil has to be provided from petroleum for 90 per cent of the world's requirements ; and, finally—the latest phase of production—hundreds of petroleum derivatives are now available to be used in manufacture of insecticides, detergents, plastics, rubber goods, paint and artificial silks, then beyond all question oil and industry to-day are inseparable and are likely to remain so for many years to come.

BLOOD GROUPS AND HUMAN EVOLUTION

DR. A. E. MOURANT, in his presidential address to Section H (Anthropology), states that, whereas in the past the study of human anatomical characters and, more recently, of blood groups, has been directed mainly towards the establishment of static classifications, we are to-day becoming more interested in the processes which have led to the development of the existing characters and of their distribution.

The external characters of the body were for a long time the only available basis for anthropological classification. They are mainly determined by heredity, but also in part by the external environment. Moreover, their genetics is complex and has been little studied. Each character appears to be controlled by a number of separate genes known as polygenes.

The blood groups are genetically much simpler and better understood : they are entirely under genetical control and unaffected by the environment of the individual. Nine genetically distinct blood-group systems are known, each comprising a number of genes, the frequencies of which vary from one community to another in a manner which permits a classification of those communities. Most of the existing information, however, refers solely to the *ABO* system. A number of other simple genetical systems are of anthropological interest, perhaps the most important being that which controls the varieties of adult hæmoglobin, including sickle-cell hæmoglobin.

Within any given area of sub-continental size, the gene-frequencies in most of the blood-group systems show an approach to uniformity, whereas those of the *ABO* system vary considerably between adjacent quite small areas, such as the counties of England. This suggests that the *ABO* groups have been subject to appreciable natural selection more recently than the others.

It is now known that certain diseases are commoner among persons of one blood group than of another, the most striking example being the greater tendency to duodenal ulcer among persons of group *O* than among those of other groups. Since these diseases are in part determined by the environment, we have here a possible mechanism of selection.

A better understood example of natural selection is that affecting normal hæmoglobin and sickle-cell hæmoglobin, controlled by a pair of allelomorphic genes. Homozygotes for the sickle-cell gene mostly die young of anæmia; but heterozygotes are less likely to die of subtertian malaria than are persons homozygous for the normal gene. Hence, under malarious conditions, selection gives rise to an equilibrium between the two genes.

By a study of characters subject to rapid selection, such as the hæmoglobins, of those not quite so rapidly selected, like the *ABO* groups, and of those blood groups which are yet more slowly selected, we may be able to trace relationships between human populations which have existed at varyingly remote times.

Even when allowance is made for the differing extent of our knowledge, there appears to be an increase in complexity in the blood groups as we go from the lower primates to the anthropoid apes, and a great increase as we go from the latter to man. We may perhaps suppose that the critical stage of evolution from ape to man took place in a limited area, and that the blood groups of the evolving race were relatively simple and adapted to the local environment. As man with his newly evolved mental powers gradually covered the Earth, so the blood groups and many other genetical characters have evolved along many different lines to meet the variety of new environments to which adaptation has been necessary.

We cannot doubt that human evolution is still going on, and its study on genetic lines has a great contribution to make to anthropology.

THE MACHINERY OF POSTURE

In his presidential address to Section I (Physiology), Prof. D. Whitteridge remarks that the very great developments in the design of servo-mechanisms during the Second World War have produced attempts to describe the activity of the nervous system in similar terms. These attempts have been resisted by those who hold that such descriptions are either valueless or already well known. One of the most attractive analogies is between head and eyes, and the gun-control platform on a battleship which may carry a telescope for observing enemy aircraft and has to be stabilized against roll and against change of course. If the telescope is stabilized against movement of the ship, the image of enemy aircraft will remain in the visual field and the observer can follow its comparatively slow movements.

It must be admitted at once that Sherrington knew as compensatory reflexes what we might describe as stabilizing reflexes or mechanisms with negative feedback. He emphasized the plasticity of the stretch reflexes of the muscles of the leg by which the weight of the pelvis can be supported in a variety of slightly different positions of the joints of the hind legs. He emphasized the sensitivity of the stretch reflex and the shortness of its latency. Nevertheless, the essential conditions for stability were not explicitly stated.

In the impressive and detailed work of Magnus on righting reflexes, we find much more stress on the presence or absence of these reflexes than on their exact performance. The persistence of righting reflexes after removal of the cerebellum is emphasized; but we have to go to the description of Dusser de Barenne to see how poorly they are then carried out, with tremors and irregular jerks.

The usual teaching is that, in the monkey and man, the labyrinthine mechanisms have become of little importance, and it has been suggested that they are inhibited by the precentral cortex. On the other hand, the reactions of normal human beings to sudden passive movement on the tilt table seem to be carried out by vestibular mechanisms and may have latencies shorter than those of cortical movements. After double labyrinthectomy, patients have 'jumbled vision' during walking or when they are wheeled over rough ground, because voluntary movement of the eyes is too slow to compensate for the passive movement experienced. During rotation of the head about the visual axis in man and the pigeon, the counter rotation of the eyes provides complete compensation; but after the movement is over, the eyes drift back. Clearly the vestibular reactions stabilize the eyes and provide a basis for the operation of fixation reflexes.

Finally, the role of the cerebellum as a stabilizing mechanism received new attention. After its removal, the latency of spinal reactions is unchanged; there are no data on the latency of rapid righting reactions, though they often show serious over-action. There is considerable evidence that the latency of cortical reactions is greatly increased, and correspondingly hopping and placing reactions are slowly and inadequately executed.

The suggestion of a series of stabilizing systems at different levels in the central nervous system cannot be extracted from the older literature, and has some usefulness in predicting and explaining the behaviour of intact organisms.

PSYCHOLOGY AND THE HUMANISTS

The claim that we can have a science of human behaviour has aroused misgivings because of the supposed implications of such a science for everyday life. In discussing these implications, Prof. J. Drever points out in his presidential address to Section J (Psychology), we must not be sidetracked by applications. Some of the latter have obviously questionable features. The refinement of technique in propaganda and advertising is not without danger, nor perhaps should we feel complacent about an educational system which sometimes seems to grade children like eggs or potatoes; but such developments are in the nature of by-products, and it is not with them that we are concerned.

Misgivings about the implications of psychology on the part of humanists and others concerned with values seem to depend upon two assumptions: (1) that science is an attempt to supersede ordinary thinking rather than supplement it; and (2) that in setting out to establish a science of human behaviour the psychologist is somehow claiming that human beings are predictable in the way that atoms or billiard balls are predictable. In point of fact, neither of these assumptions seems to be justified. The former is a result of over-simplification, and arises from a belief that in any situation there is always some one statement or theory which is 'really true', all others being partial or false. But even within science this does not hold.

The scientist describes as accurately as he can certain features of the world around him, and then devises systems or models through which the economy of inference replaces the laborious cataloguing of facts; that is to say, he invents a way of talking or thinking which is very useful for certain purposes, among them prediction and control. But this is not to say that he discovers what things 'really' are. My neighbour is really my neighbour just as he is really *Homo sapiens*, and really hydrocarbons, water, and some trace elements. The emergence of a science of behaviour does not seem to alter this situation in any important way, and it is a situation which has existed since science began.

The second assumption arises from the widely held view that science is mainly concerned with causes; but this is not the primary concern of science. The search for causes is a diagnostic enterprise carried on by the practical man—the medical practitioner, for example, or the engineer—rather than the physiologist or physicist. When we talk about the cause of anything we generally mean some particular item in its history without which it would have turned out differently. More especially it is an item which we can control or change, since every event has a multitude of causal ancestors. The reliable identification of this kind of item is clearly necessary for control over our environments, and science by clarifying the structure of events makes it much easier; but science itself need not talk about causes at all. All that we need assume when we embark upon a science of behaviour is that the object of our study makes some kind of sense, or in other words, is not merely random. This is an assumption which the humanist no doubt shares.

Perhaps the real reason for some of the contemporary uneasiness is that with the abdication of philosophy, which has become a specialism among specialisms, the ordinary man is tending to turn to the scientist, and perhaps particularly to the psychologist and psychiatrist, for answers to quite general questions. It may be that some are too ready to give him what he wants; but the real solution seems to lie in a bolder and more positive approach on the part of those who at present seem to have nothing to offer us between the rigours of logical analysis and a sort of nostalgic antiquarianism.

QUATERNARY HISTORY AND THE BRITISH FLORA

In his presidential address to Section K (Botany), Dr. H. Godwin points out that in so far as time is required for the processes by which plants and animals attain their distribution areas, so far the problems of biogeography must be historical problems.

Investigation of the Quaternary Period, and especially that part of it which includes the latest glaciation, the succeeding 'Late-glacial' period, and the Post-glacial period, has been applied with great effect to the study of plant geography in the British Isles. In the first place, it has enabled us to reconstruct former climates and geographical conditions during those phases of plant migration, expansion and reduction which gave rise to present ranges of area; and in the second place it has given us a chronological scale against which a great number of sub-fossil plant remains have been effectively dated, sometimes in years, sometimes by reference to a defined period of climate, vegetation, archæological culture or of geological events. Important techniques serving these purposes are pollen analysis and radiocarbon dating, the former serving at once to give a chronological scale and to provide direct evidence of the former range of certain plants. For the purposes of his address Dr. Godwin considers the data thus acquired for a few species only.

It has been strongly urged by many botanists that the rich collection of arctic-alpine plants now found in such mountain areas as Ben Lawers, Ben Bulben, Teesdale and Cwm Idwal are so localized because they were nunatak refugia during the glaciations. The dated records for such species as *Thalictrum alpinum, Dryas octopetala, Salix herbacea, Betula nana* and *Polemonium coeruleum* dispose effectively of this hypothesis, for they prove that these species were widely present in the lowlands of Britain in the Late-glacial period *after* the ice had vanished. Their restriction of range is a Post-glacial phenomenon associated, it may be guessed, with expansion of continuous deciduous forest, with increasing temperatures, with soil deterioration and with blanket-bog formation on high mountain areas. The records likewise prove the extinction during this period of certain plants present in the Late-glacial, so that their absence (as of *Betula nana* from Ireland) is due to extinction and not failure of migration to these shores.

Abundant evidence is forthcoming that a large part of the population of weeds and ruderal plants in Britain was naturally present also in the Late-glacial period, and that after suppression in the closed forest period they began re-expansion when prehistoric agriculture opened the woodland cover.

Likewise the records give evidence for the expansion of thermophilous plants (such as *Najas marina*) in the middle Post-glacial period, and retraction after the climatic optimum.

The methods of Quaternary research allow us to date the formation of the North Sea to a period about 8,000 years ago, and to prove that there was a long period of temperate climate and open vegetation before this, and during which dry-land immigration of plants and animals from the Continent of Europe was possible. Not only so, but the records strongly indicate that the bulk of the British flora was indeed present during this time, and that subsequent overseas immigration has been relatively unimportant until recent historic time.

Such studies as these give a new and firm basis for the study of biogeography of all those temperate regions affected by the Quaternary glaciations.

THE IMPACT OF BRITISH EDUCATION ON THE INDIGENOUS PEOPLES OF OVERSEA TERRITORIES

IN his address to Section L (Education), Sir Christopher Cox directs attention to the paradox by which, as British Colonial policy achieves its purpose and our direct responsibilities for the education of other peoples in different parts of the globe contract with the growth of self-government, the calls made upon Britain's educational resources visibly multiply. The Colonial relationship as it fades out may well be replaced by a continuing system of special intimacy in which more of us than ever before may find ourselves called upon to take some part. A wider understanding of our Colonial educational relationship therefore has its bearing on the effectiveness of the help we can give in this period of transition to the post-Colonial epoch.

Britain's official concern with 'Colonial educational policy' is of comparatively recent growth. In early days, in contrast with official policy in India, it was for the most part left to missionaries to introduce Western schooling to the indigenous Colonial peoples, unless exceptionally such factors as the predominance of a non-Christian world religion brought about early planning by a Colonial Government. But after the First World War the position was transformed. Focused first on Africa, and later on the Colonial territories as a whole, the Secretary of State's Advisory Committee on Education came into being, representing a wide range of professional experience in the United Kingdom, and from the start was designed to exercise a powerful influence upon policy. The Colonial Educational Service was established, and special training devised. Most famous of the Committee's many memoranda was its first—the White Paper of 1925 on Educational Policy in Tropical Africa. With access to the findings of anthropology and to the history of British education in India, its authors sought to spare the African peoples those deep-seated but wholly unintended distortions and injuries to which our lack of experience had contributed elsewhere. Keynotes were environmental adaptation and the grafting of Western schooling on to the indigenous stock.

But intentions and fulfilment are very different things. It is suggested that our effort to apply to African educational policy lessons learnt from experience in India came twenty or thirty years too late. Western schooling had already taken root and local reactions to it had begun to take shape. Once that has happened, the fundamental factor becomes less the policy of government than the attitude of the governed. "In the long run," in the words of a *Round Table* contributor, "Africa will take what it wants, digest it slowly, and assimilate what it does not spit out again." Selection there might have to be: but selection by Africans, in Africa—not for Africans, in Britain. The general position all over British Africa to-day, despite its many remaining backward areas, is increasingly one in which Africans have set their hearts upon a complete Western education as they believe it to be, while in West Africa educational progress has been identified with the post-War march towards self-government. It is these factors that determine the acceptability of what we have to offer to-day.

Against this background certain features of the Colonial educational scene to-day stand out. Demand altogether outstrips the capacity of the territories to meet it. The fact that their resources at present bear no comparison with those of an industrial country inexorably limits their educational development to a fraction of the comprehensive system reached by a modern State after centuries of growth; yet many of them are moving rapidly towards self-government. Sir Christopher refers to the resulting central educational dilemma, in which the rival claims of quality and quantity contend in a setting of exiguous resources and insatiable demand—a problem which, like that of the allocation of priorities between educational and economic investment, is being discussed in more detail at subsequent symposia. It is urged that, by and large, our duty is to introduce the Colonial peoples to the general pattern of the system that we know and believe in, and to indicate ways in which we ourselves think that system can be adapted to local necessities as well as local wishes; there are certain fields, most notably universities, secondary grammar schools and teacher training, in which what we have to offer must be really first-class if the health of these young educational systems is to be assured. Reference is made to the crucial importance of technical education and to the special requirements of girls' education and adult education.

In recent years educational growth and national emergence have progressively reduced the need for formal advice from the Secretary of State, but have multiplied occasions for contact, consultation and practical help. Of outstanding importance has been the assistance given in the field of university education by the Inter-University Council for Higher Education Overseas and by the University of London. Exceptional in their scale and complexity were the contacts culminating in the Cambridge Conference on African Education of 1952. But in general the demands upon Britain for help are probably now more numerous, varied and exacting than ever before—in the increased call for educational staff, in the flow of oversea students, in the two-way movement of mature professional visitors coming to Britain and of *ad hoc* missions or experts going out from it. Our contribution, whether here or overseas, will be the more effective if we are aware of the way in which we have been mixed up together and understand some of the factors involved in the working out of the Colonial educational relationship. The verdict of history on the Colonial educational work of Britain cannot yet be given; but the way in which we go about this in its closing stages will determine whether the educational links between many young countries and our own will be only those of history, or whether a new and active relationship of mutual benefit among partners will have emerged.

THE INFLUENCE OF MAN ON SOIL FERTILITY

MR. G. V. JACKS, in his presidential address to Section M (Agriculture), directs attention to the dominant influence of towns on the evolution of the soil under human occupation.

Man's first action on the soil is usually that of a shifting cultivator or nomad, at which stage he scarcely affects the existing balance of Nature. As population increases and the land fills up, he adopts settled agriculture, which upsets the biotic balance. The first stages of settled agriculture are inevitably soil-exhausting, and human societies tend to develop social systems which keep soil exhaustion under control. This was the reason for the rigid medieval three-field system of agriculture, and is also the reason for the present-day appearance of soil-conservation districts, with their communal rules for checking soil exhaustion, in many countries that have not yet reached the stage at which the positive influence of towns in creating soil fertility makes itself felt.

The growth of towns has a powerful influence on the evolution of the soil. Towns create far more wealth than agriculture can create, a rising standard of living and a greater demand for the produce of the soil. To begin with, this results in an accelerated exhaustion of the soil; but if the wealth of the towns increases, a stage is reached at which it pays farmers to increase output per acre and, therefore, to raise soil fertility. Every successful, mature civilization has enormously increased the fertility of the soil.

In Britain a gradual change-over from soil-exhausting to soil-conserving agriculture began with the enclosure of the 'common fields' and the rise of the wool-trade. Subsequent improvements in agriculture and soil fertility were brought about because the growing urban population was able and willing to pay for the food and clothing it needed. In North America the earlier rapid exhaustion of the soil has recently been succeeded by a substantial increase in soil fertility (measured by crop yields) as the wealth of American industry begins to flow back into the soil. In the U.S.S.R. the rapid expansion of industry is still starving the land, and no increase in yields is yet apparent. South Africa and Australia, with increasing industrialization, seem to have reached the turning point between soil exhaustion and soil conservation. Future development of industry in India might have a favourable influence on soil productivity, which is at a low level. Much of the rest of the tropics is still at the stage of shifting cultivation, though many Colonial countries have begun to practise settled agriculture and are suffering severe soil exhaustion as a consequence. Social systems are being evolved to check this exhaustion. It seems improbable, however, that the general level of tropical soil fertility can be raised without the backing of large, well-to-do urban populations.

Mr. Jacks ends by asking whether the world, a hundred years hence, will be able to feed the 6,000 million people who may then be living in it, and answers yes, provided most of them live in towns and produce enough wealth to pay for the food they require.

LOCAL SOCIETIES IN THE COMMUNITY OF TO-DAY

In his presidential address to Section X (Assembly of Corresponding Societies), Dr. F. J. North suggests that a meeting of delegates from corresponding societies is an appropriate occasion for considering the decline in membership to which the reports of local societies refer with increasing concern, and for asking whether the decline is temporary or indicative of a permanent trend, and what can be done to arrest it.

The history of local societies shows that they were a product of an age when conditions were very different from those which obtain to-day. It was an age of leisured amateurs with both time and means to follow cultural pursuits; an age when the 'fragmentation' of science had scarcely begun, so that an educated person could not only take an intelligent interest in almost any topic that might be considered at the meetings of a local society, but also play a useful part in contributing to discussions or engaging in original work.

The spread of education has provided a greater potential membership for local societies; but recruitment has been hindered for a variety of reasons. There has been a great increase in the number of cultural and professional organizations, and there are new claimants upon leisure time and increased facilities for enjoying it. All these were making themselves felt long before the cinema, sound broadcasting and television entered the field as formidable competitors.

With the view of assessing the relative importance of the circumstances affecting local societies, Dr. North reviews changes in the membership of the Cardiff Naturalists' Society (chosen because it is the one he knows best), indicating the causes to which the fluctuations are due and the effect of the foundation of a rival scientific society in the city. This survey leads to the conclusion that, while the community of to-day would be vastly poorer if local societies were crowded out of existence, the decline in their present strength and popularity is in large measure due to failure to move with the times.

Suggestions are offered concerning the ways in which adaptation to the new conditions will affect lecture programmes, the publication of transactions or proceedings, the co-ordination of the activities of societies by unions and federations, and will involve meeting counter-attractions like broadcasting and television by action designed to profit from the curiosity and interest their programmes create.

Whatever may be done to retain present interest, the future of local societies will depend upon the recruitment of members from among those who, now of school age, will be the adults of another decade. It is not only necessary to stop leakage, but even more necessary to take steps to ensure an adequate intake. With this object in view, advantage should be taken of the interest aroused among senior pupils by the service rendered to schools by museums; this is greater than many people suppose. In the National Museum of Wales, for example, a staff of fifteen, with the active support and guidance of the Director and the departmental staff, is solely concerned with school activities. Being organized by a museum, the service is able to emphasize the inspirational interest of the subjects dealt with, as well as provide assistance to those who are preparing for examinations. It is hoped in this way to create, during school-days, interests that will remain in after-life, and there is ample evidence that this hope is being fulfilled.

Many other museums engage in school services on varying scales but with similar objects in view, and local societies have much to gain by cultivating closer relations than may now exist with museums on one hand and schools on the other, with the view of tapping this reservoir of potential members.

MICRO-ORGANISMS FROM DECAYING SEAWEED

By PROF. E. G. PRINGSHEIM
Pflanzenphysiologisches Institut, Göttingen

THERE are certain places where a peculiar assemblage of micro-organisms can regularly be found. Such are cow-droppings, which harbour the large bacteria *Caryophanon* and *Lineola*[1] and species of *Vitreoscilla*[2]. More varied are the contents of the rumen of ruminants and the cæcum of rodents[3] with their specialized populations of flagellates, yeast-like organisms, the giant bacterium *Oscillospira caviae*, and others. There are the slimy exudations of wounded tree-trunks, the habitats of the colourless chlorella-like *Prototheca* and other specially adapted small algae.

An interesting community of colourless organisms, apart from bacteria, can also generally be found on seaweed, particularly *Fucus*, when these are uprooted and partly exposed to the air. The thalli die, and the sea water covering the lower portions soon teems with bacteria, among which the following organisms are nearly always present.

Nitzschia putrida (Cohn) Benecke[4], perhaps the only colourless diatom, swarms gliding out of drops of the putrid fluid or bits of thallus, when these are put on the surface of sea-water – agar. By moving away from the centre of inoculation on to the sterile agar, the cells purify themselves and can easily be picked up and grown in bacteria-free culture on sea-water – agar enriched with peptone, yeast extract or the like.

At the same time, various amœbæ creep away from the inoculum, especially when the *Fucus* material has been kept in the laboratory for some time. They too purify themselves when gaining the sterile parts of the agar surface; but when thus freed from bacteria, they no longer multiply but encyst. As with fresh-water amœbæ, there is something as yet unknown lacking in their diet when bacteria are absent, and so far it cannot be provided in any other way.

An interesting organism, known for a long time from water in contact with decaying *Fucus*, is *Gyrodinium cohnii* (Seligo) Schiller. Küster[5], in an article entitled "Eine kultivierbare Peridinee", described how its cells, transferred to a *Fucus* decoction – agar plate, divided once or twice. This was, at that time, considered an appreciable performance, although Küster could not make the cells excyst and did not, therefore, obtain any further development. Purified with the help of the washing technique[6], *Gyrodinium cohnii* can be induced to multiply in a medium containing yeast digest (Pringsheim, 1955), sodium acetate and peptone in sea water and encysts only after heavy multiplication, the cysts germinating in fresh medium. This peridinian is devoid of photosynthetic pigments but, as a reserve, stores plenty of starch. Its nutrition is therefore comparable to that of *Polytoma* and *Polytomella*, colourless members of the Volvocales, and of *Chilomonas*, a colourless cryptomonad. The substances used by *Gyrodinium cohnii* to form starch will, I hope, be established by further investigations.

While the organisms so far mentioned live in very polluted water, *Oxyrrhis marina* Duj., a doubtful peridinian which lives on particulate food and is more animal- than plant-like, occurs only when there is not too much putrefiable material. It can be grown with small marine flagellates as its food. Replacement of zootrophy by osmotrophy has not yet been achieved.

There are in this community also some organisms which have been discovered only recently. A member of the Vitreoscillaceae[4], only one species of which had previously been extracted from a marine habitat, was observed several times in the putrid fluid between *Fucus vesiculosus* from Kiel Bay (Kieler Förde) on the Baltic, when these had been kept in a large dish half covered with sea water. It could be grown from filaments isolated with the capillary pipette and transferred to peptone – yeast extract – sea water – agar.

In some of the crude cultures of seaweeds in sea water, colourless, non-motile filaments of great length were detected. Colonies on agar were obtained by repeatedly washing relatively short lengths of trichomes and transferring them to the surface of peptone – sea water – plates, then streaking with a loop. The colonies were dense, brain-like, non-translucent and composed of one very long filament. This can be demonstrated by touching a colony with a wire-needle or capillary pipette, when a continuous thread of great length can be pulled off the agar.

This organism was *Leucothrix mucor* Oersted, described as early as 1844 under this name and recently grown in pure culture by Harold and Stanier[7], who clarified its history, relationship and biology. Its freeing of bacteria is greatly facilitated by the washing procedure before plating. The organism produces short lengths of cell-chains which glide along solid surfaces and serve as an efficient means of propagation. In this respect it resembles *Thiothrix*, to which it is apparently related, as Harold and Stanier have demonstrated. *Leucothrix* is very variable according to conditions. In rich nutrient solutions, the filaments become very long; in poor media they soon cease to grow, and their terminal portions are then transformed to beaded chains which break up into short lengths or hormogonia. The formation of a rosette by the propagative organs specially investigated by Harold and Stanier is characteristic.

Much more difficult to cultivate is *Ciliophrys*, a heliozoon-like creature with spherical cells beset with great numbers of extremely delicate radiating plasmatic strands. The species found between decaying *Fucus* material seems to be *Ciliophrys marina* Caullery 1909. It can produce a flagellum, with the help of which it swims rapidly through the water, changing to a spindly shape, generally with a roundish front and a conical posterior end which may be divided into several irregular, pointed cones. The conditions in which it ceases motility and resumes swimming are not yet clear. Cultivation was possible with the help of soil–water putrefaction cultures, but subculturing was not always successful.

There are also in this community a number of ciliates and flagellates, and some bacteria, which seem to be worth studying, so that biologists interested in this kind of work may find it worth while to watch the biotype in its various stages of development.

THE QUESTION OF CORRELATION BETWEEN PHOTONS IN COHERENT LIGHT RAYS

By Prof. ERIC BRANNEN and H. I. S. FERGUSON
Department of Physics, University of Western Ontario, London, Canada

CONSIDERABLE interest has been aroused in this question, especially since the experiments of R. Hanbury Brown and R. Q. Twiss[1] showed a correlation, unexpected by many, between the current outputs from two photoelectric detectors viewing coherent light rays. On the other hand, A. Ádám, L. Jánossy and P. Varga[2] performed a similar experiment using "an amplifier with a resolving time of 2 μsec." and observed no such correlation.

In this laboratory we have been performing coincidence experiments[3] on photons emitted in cascade transitions from optical sources using apparatus of resolving time $2\tau = 10^{-8}$ sec. With this apparatus[4], which is now standard in nuclear physics, time delays can be inserted in either photomultiplier channel, and so a distinct answer to the question of time correlation can be obtained. Our apparatus has observed true coincidences in the above case of optical transitions in cascade. This is of prime importance, since our negative results with coherent light rays can have meaning only if the apparatus has been shown to be capable of, and efficient in, observing 'true' coincidences.

The experiment reported here was designed to duplicate so far as possible the optical arrangement of Brown and Twiss, up to and including the photomultipliers. It is in the electronic detection of coincidences between the outputs of the photomultipliers in which we differ from them. Furthermore, our apparatus compares pulses due to the detection of individual photons by the photomultipliers, rather than an integrated output due to large numbers of photons. We also feel that the Brown and Twiss experiment does not sufficiently reject the possibility that the correlation they observed in the 'photocathodes superimposed' position was due to rapid intensity fluctuations in the source. It seems probable that classical wave theory would predict correctly this case, since both photomultipliers would be observing the same part of the source, and since the fluctuating part of the photocurrent was observed. Furthermore, no correlation would be observed in the 'photocathodes not superimposed' position if their movable photomultiplier then viewed another region of the source, which was comparatively steady, or the intensity fluctuations of which were not correlated with the previous region. Although we do not feel competent to answer the question, it occurs to us that the radio telescope of Brown and Twiss could be working in a similar manner if the galactic source of radio noise was fluctuating in intensity with different regions fluctuating, for example, independently. It should here be emphasized that random coincidences are evaluated in our experiment by insertion of a time delay in one channel much greater than the resolving time of the apparatus. This means that such macroscopic intensity fluctuations in the source would not affect the results of our experiment.

The experimental arrangement is shown in Fig. 1. *S* is a high-pressure Hilger mercury arc. The image of the arc is focused by means of an *F*2 Zeiss Biotar lens *L* on to a small pinhole *H* of diameter 0·25 mm. The light is filtered by a Baird interference filter (λ4358 A.) and the appropriate Wratten filter, at *F*, so that essentially monochromatic light falls on the pinhole. It was found that a good lens free of aberrations is essential in order to get a uniform beam free of striations falling on the half-silvered mirror *M*. The light transmitted by the mirror is detected by a 1*P*21 photomultiplier P_1, and that reflected is detected by a similar photomultiplier P_2. The areas of the two photocathodes are limited by identical rectangular apertures A_1 and A_2, 4 mm. by 8 mm. Single photons detected by the photomultipliers give rise to voltage pulses which are shaped (5×10^{-9} sec. duration), and delayed by coaxial cables L_1 and L_2. They are mixed in the coincidence stage and an output pulse obtained if they are in time coincidence at the coincidence stage. In the diagrams, positive delay refers to P_1 pulses delayed with respect to P_2 pulses, and negative delay vice versa. The total coincidence rate *C* as a function of delay, and the counting rates C_1 and C_2 in each channel, were recorded. Throughout the experiments C_1 and C_2 remained sensibly constant.

The following set of experiments was carried out in order to test the equipment and to test for correlation between photons: (*a*) cable attenuation corrections; (*b*) coincidence rate as a function of

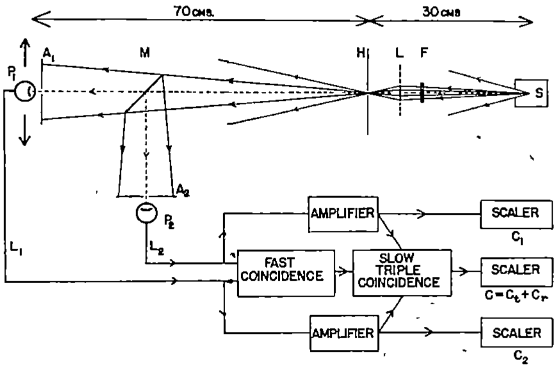

Fig. 1. Simplified diagram of apparatus

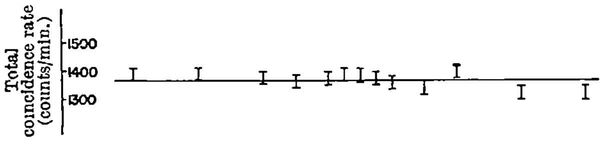

Fig. 2. Total coincidence rate versus delay, 'photocathodes superimposed'

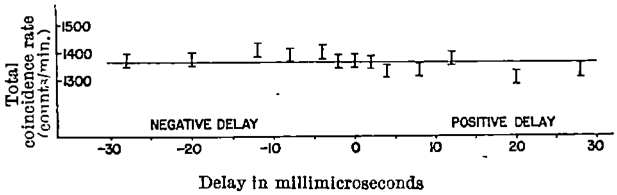

Fig. 3. Total coincidence rate versus delay, 'photocathodes not superimposed'

delay, 'photocathodes superimposed'; (*c*) coincidence rate as a function of delay, 'photocathodes not superimposed'; (*d*) coincidence rate as one of the photomultipliers scans the beam; (*e*) coincidence rate as intensity of the source varied; (*f*) prompt resolution curve for the coincidence apparatus. In all the experiments the apparatus was functioning stably and consistently.

The cable attenuation corrections were obtained with the photomultipliers observing independent sources, and in no case are they greater than several per cent. These have been applied to all the following results.

With P_1 and P_2 in the 'photocathodes superimposed' position, the total coincidence rate as a function of delay was recorded and the results of Fig. 2 obtained. It is noted that within the statistical error of a probable error of 1 per cent, there was no increase in coincidence counting rate at zero delay relative to long delays.

The 'photocathodes not superimposed' position was obtained by moving P_2 laterally a distance of 12 mm., which is equivalent to three times the slit width. The total coincidence rate as a function of delay was again recorded, and the results plotted in Fig. 3. Again there was no increase in coincidence counting rate at zero delay relative to long delays. It is readily apparent that the two sets of results presented in Figs. 2 and 3 are indistinguishable.

In order to ensure that the image position had not been missed, P_1 was moved in steps small compared to the slit width and the total coincidence rate recorded for zero delay. The flat curve of Fig. 4 was obtained. The beam was quite uniform as shown by the total side-channel count from P_1, which remained constant (variation less than 1 per cent) over the whole width of the beam. There is no increase in coincidence counting rate at the 'photocathodes superimposed' position.

A further check was carried out—the intensity of the light source was varied, and the coincidence rate at zero delay, and the side-channel rates, recorded.

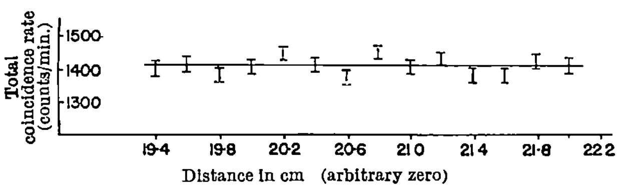

Fig. 4. Total coincidence rate at zero delay versus position. (Photomultiplier P_1 moving in steps across the image)

The coincidence rate C was proportional to the product C_1C_2 consistent with the coincidence rate being pure random[5] (random rate $C_r = 2\tau C_1C_2$).

Finally, to ensure that the apparatus was functioning properly, resolution curves (Fig. 5) were obtained before and after the previous experiments. Stilbene crystals were placed in front of the photomultipliers and a cobalt-60 source (1·17 and 1·33 MeV. gamma rays in cascade) used as a source of prompt radiation.

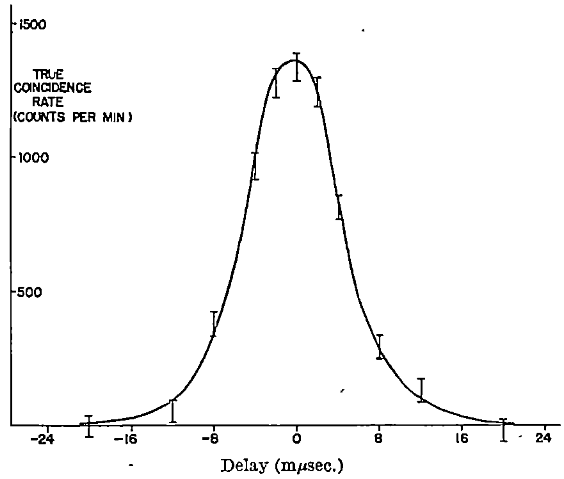

Fig. 5. Prompt resolution curve

From these experiments one can place an upper limit on the fraction of photons acting in an anomalous manner. The side-channel rates C_1 and C_2 were each $(5{\cdot}00 \pm 0{\cdot}05) \times 10^4$ counts per second. The coincidence rate was $24{\cdot}0 \pm 0{\cdot}4$ counts per second. Even if one goes to eight times the probable error there can be no more than three true coincidences per second. Since the 1*P*21 photomultipliers have a photoelectric efficiency of about 10 per cent at a wave-length of 4358 A., this means that the probability is less than 1 in 10^7 that more than 0·03 per cent of the photons detected are in true coincidence. (Ádám *et al.*[2] estimated that less than 0·6 per cent of the photons are in time coincidence allowing a deviation of three times the probable error. In our case, using three times the probable error, less than 0·01 per cent are in time coincidence.)

In conclusion, our experiments indicate that there is no correlation (less than 0·01 per cent) between photons in coherent light rays.

We are indebted to Dr. W. Wehlau, in the Astronomy Department at this University, who brought this controversial matter to our attention. Discussion with him on this and allied subjects has proved most valuable.

Note added in proof. It would appear to the authors, and also to Prof. Jánossy (private communication), that if such a correlation did exist, it would call for a major revision of some fundamental concepts in quantum mechanics. This was, of course, the reason why these experiments were performed.

Density and Expansivity of Solid Argon

A FULL knowledge of the thermodynamic properties of some simple solid, such as a solidified inert gas, is necessary for the satisfactory development of a rigorous lattice dynamics. When a simple inter-atomic potential containing two constants is applied to a given substance (see, for example, Barron and Domb[1], Henkel[2]), it is necessary to know at least the density and energy of sublimation at absolute zero so as to determine the constants. In order to verify the theory in detail, it is then necessary to measure three independent quantities such as C_p, α and $\varkappa_s$, where α is the volume expansivity and $\varkappa_s$ is the adiabatic compressibility.

For various reasons, argon is the most suitable substance for such a study; but until recently only one of the three coefficients, C_p, has been known accurately for the solid[3]. Last year, Stewart[4] determined the isothermal compressibility ($\varkappa_T$) at 65° and 77° K. and Barker and Dobbs[5], in this laboratory, determined $\varkappa_s$ over the same temperature-range by an ultrasonic method. We have now measured the density between 20° and 80° K., and have thus obtained values of α.

Up to 60° K. we have used the X-ray method of measuring the lattice parameter by taking Debye–Scherrer 'powder' photographs. Details of the experimental arrangement as applied to metallic specimens at low temperatures are given elsewhere[6]; in the present work, a polycrystalline specimen of argon was deposited from the vapour on an aluminium wire subjected to precise temperature control. Recrystallization became evident at about 60° K., so that the method became increasingly inaccurate; and above this temperature we have determined the bulk density of polycrystalline specimens by finding the volume of gas at N.T.P. required to fill with solid argon a glass bulb of about 3 c.c. maintained at a given temperature. All the solid specimens used were transparent and free from visible flaws. The argon was stated by the British Oxygen Co., Ltd., to be of at least 99·999 per cent purity.

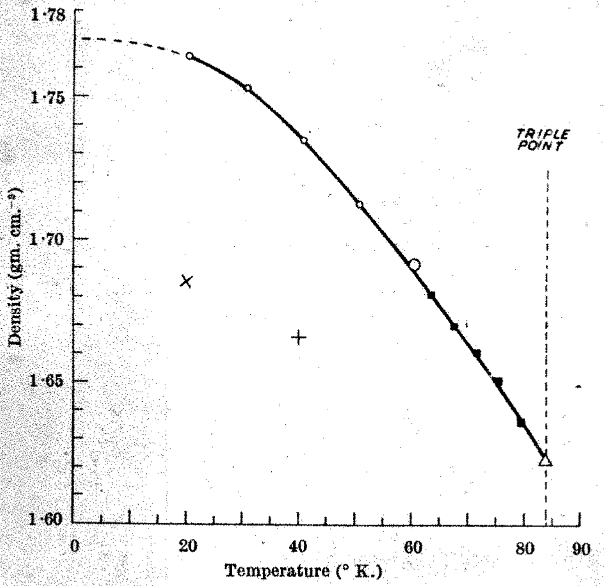

Fig. 1. Density of solid argon. Present results: ○, X-ray method. ■, bulk density method. Earlier results: △, Clusius and Weigand; ×, de Smedt and Keesom; +, Simon and von Simson

The results are shown in Fig. 1; it will be seen that the two methods give good agreement where they overlap, within our estimated accuracy of about 0·001 gm. cm.$^{-3}$. Our results differ appreciably from those of the X-ray measurements at single temperatures of de Smedt and Keesom[7] and Simon and von Simson[8], but agree with the value of the density at the melting point deduced by Clusius and Weigand[9] from observations of the melting curve and of the density of the liquid.

In the following table we summarize our results for the density (ρ), and give estimates at four temperatures of the expansivity and of the Grüneisen parameter $\gamma = \alpha V/\varkappa_s C_p$.

T (° K.)	20	40	60	80
ρ (gm. cm.$^{-3}$)	1·764	1·737	1·691	1·636
$\alpha \times 10^4$ (deg.$^{-1}$ C.)	4	12	15	18
γ	2·0	2·7	2·8	2·4

The values of α, much larger than suggested by the previous independent measurements at three temperatures, account for the large difference between the results of Stewart for $\varkappa_T$ and those of Barker and Dobbs for $\varkappa_s$, since the ratio $\varkappa_T/\varkappa_s = 1 + \alpha^2 TV/\varkappa_s C_p$ rises to a maximum of 1·45 at the melting point. The large ratio (equal to C_p/C_v) also accounts for the unusually high value of C_p (8·5 cal. mole^{-1} deg.$^{-1}$ C.) found by Clusius[3] at the melting point, since C_v is now reduced to 5·9 cal.mole^{-1} deg.$^{-1}$ C., the classical value. The value of the Grüneisen parameter appears to go through a maximum, with an average value of about 2·5. More accurate experiments at the lower temperatures are required before the detailed form of this variation can be known.

It is important to note that our results lead to an estimate of the density at absolute zero of 1·77 gm. cm.$^{-3}$, corresponding to a lattice parameter of 5·31 A., as compared with the previously accepted value of 5·40 A.

Theoretical Calculations on Solid Argon

It is well known that a knowledge of the second virial coefficient of a gas does not suffice to specify the intermolecular potential of the constituent molecules. In fact, even if a simple formula of Mie–Lennard-Jones type is used as an approximation to the potential, the parameters are not uniquely determined by the second virial coefficient. On the other hand (as mentioned in the preceding communication) certain elementary properties of the solid state are sufficient to determine these parameters uniquely, and further observations on the solid and gaseous states can then be used as a test of the region of validity of this type of approximation to the potential. The recent development of experimental technique enabling data on the solid state to be determined with accuracy over a wide range of pressures and temperatures has provided valuable material for theoretical analysis.

When the isotherms for solid argon at high pressures determined by Stewart[1] at the Massachusetts Institute of Technology became available, one of us (I. J. Z.[2]) undertook detailed calculations to determine how the results compared with the theoretical predictions, and, if necessary, to modify the estimates of intermolecular potentials for the inert gases concerned. Although quite good agreement was obtained, the form of potential used was not completely satisfactory because of the uncertainty in the value of the density at absolute zero. The present accurate experimental results obtained at Queen Mary College for argon enable this uncertainty to be removed, and further detailed comparisons to be made between theory and experiment for this substance.

We have used the following approximation to the intermolecular potential energy:

$$\begin{aligned} \varepsilon(r) &= \lambda/r^{12} - \mu/r^{6} \\ \lambda &= 1{\cdot}63 \times 10^{-7}\ \text{A.}^{12}\ \text{erg.} \\ \mu &= 1{\cdot}05 \times 10^{-10}\ \text{A.}^{6}\ \text{erg.} \end{aligned} \qquad (1)$$

To calculate the thermal expansion and Gruneisen's γ ($= \alpha V/\varkappa_T C_v$ or $\alpha V/\varkappa_s C_p$), we have used the approximation of Henkel[3]. This approximation is of Einstein type but takes account also of anharmonic effects; it should be reliable at temperatures not too low compared with the Debye θ value. The results are as follows:

T (° K.)	20	40	60	80
ρ (gm. cm.$^{-3}$)	1·764	1·732	1·690	1·634
$\alpha \times 10^4$ (deg.$^{-1}$ C.)	4·6	10·5	14·6	20·0
γ	2·03	2·62	2·86	2·50

These are to be compared with the experimental values of the preceding communication.

It will be seen that the theoretical calculations are in good agreement with the experimental results. Calculations at higher pressures based on the above estimate of the intermolecular potential are also in good agreement with experimental isotherms given by Stewart[1]. A further check on the estimate of the potential is provided by the Debye θ value for solid argon at low temperatures. This can be calculated approximately and simply[4] for a potential of the form (1) and yields the value of 80° K., in good agreement with the experimental value derived by R. W. Hill[5] from measurements of the specific heat of solid argon at low temperatures. The values of λ and μ given in (1) are very close to those determined recently by Whalley and Schneider[6] from data for gaseous argon.

We may thus conclude that theoretical calculations of solid-state data based on the intermolecular potential (1) give results in reasonable agreement with experiment. Further experimental data, particularly at high pressures, would be desirable to provide a more searching test of the theory.

Nuclear Spin of Americium-241

During the recording of the spark spectrum of americium[1] in the third order of the Baird three-metre grating spectrograph, a number of spectral lines appeared as four resolved components of a probable six-member flag pattern. While describing the performance of a 30-ft. Paschen–Runge spectrograph, Tomkins and Tomkins[2] have published a photograph of the Am I line at 6405 A. showing it resolved into six components. The six component flag patterns, which lead to a nuclear spin of 5/2 for $_{95}\text{Am}^{241}$, have been confirmed by interferometric studies.

In the present investigation americium was excited in a hollow cathode cooled with liquid nitrogen. High dispersion was achieved by crossing a Hilger Universal Prism spectrograph with Fabry–Perot étalon plates coated with $\lambda/4$ layers of cryolite and zinc sulphide. A series of different spacers were used for eliminating errors due to overlapping orders. Fig. 1 shows the six components of the Am I lines at 4662·80 and 4681·67, the separations between the components being 0·230 ± 0·0015 cm.$^{-1}$, 0·212 ± 0·001 cm.$^{-1}$, 0·184 ± 0·0015 cm.$^{-1}$, 0·147 ± 0·002 cm.$^{-1}$, 0·104 ± 0·003 cm.$^{-1}$, and 0·274 ± 0·001 cm.$^{-1}$, 0·226 ± 0·002 cm.$^{-1}$, 0·180 ± 0·001 cm.$^{-1}$, 0·138 ± 0·002 cm.$^{-1}$, 0·101 ± 0·002 cm.$^{-1}$, respectively.

Since these and other hyperfine separations show a marked divergence from the interval rule, a relatively large quadrupole-moment is expected for americium.

On the assumption that the $5f_{5/2}$ shell is filled preferentially to the $5f_{7/2}$, the value of a nuclear spin of 5/2 for $_{95}\text{Am}^{241}$ is in accordance with Klinkenberg's[3] nuclear shell structure tables which are based on

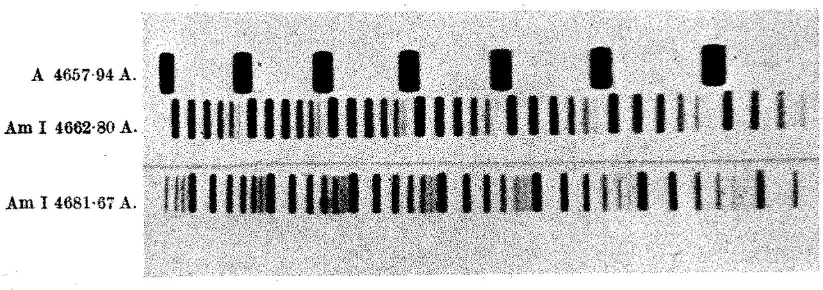

Fig. 1. Hyperfine structure of Am I lines at 4662·80 and 4681·67 A.

the single-particle nuclear shell model of Mayer[4]. This assumption is supported by the reported spin of 5/2 [5] for the odd proton nucleus of $_{93}$Np^{237}. Hence it would appear that the nuclei of $_{95}$Am^{241} and $_{93}$Np^{237} have a ground-state of $f_{5/2}$.

I am indebted to Mr. J. Ring of the Physical Laboratories, University of Manchester, for coating the Fabry–Perot plates and to Mr. N. Jackson of the Chemistry Division of this Establishment, for the preparation and purification of the americium.

Separation of Particulate Materials into Size-Ranges

DURING an experiment a beaker was used for collecting a stream of small glass spheres issuing from a chute. A number of the spheres escaped over the edge of the beaker, after rebounding from the layer of material in the bottom, and on examination this fraction was observed to be of considerably more uniform size than the original sample; an observation which suggests a simple method for the separation of non-cohesive particulate materials into sized fractions.

The following test was then carried out.

Glass spheres having diameters of 0·02–0·06 in. were allowed to fall from a funnel into a polythene beaker 3 in. diameter and 3½ in. high, the height of fall being 12 in. The polythene beaker was placed within a beaker of 1-litre capacity which acted as a receptacle for the separated fraction.

The material was supplied until the inner beaker was filled to a depth of 1½ in., when the flow was stopped, the beaker emptied and the process repeated.

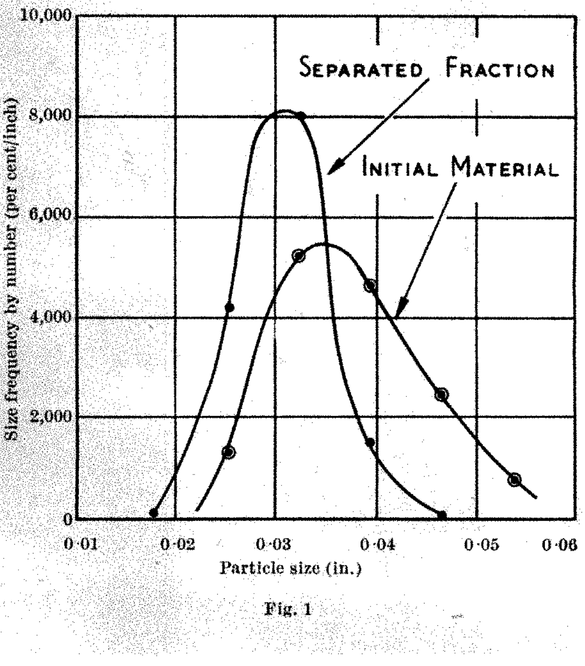

Fig. 1

The size-distribution curves for the original material and the separated fraction are given in Fig. 1.

In a further test 800 gm. of steel balls of ⅛ in. diameter and 200 gm. of steel balls of $\frac{1}{16}$ in. diameter were mixed. 7 gm. of the $\frac{1}{16}$-in. diameter balls, completely free from ⅛-in. diameter balls, were recovered after one pass of the mixture.

It is interesting to note that a possible explanation of the phenomenon is that in the manifold collisions which occur when the falling spheres are brought to rest, the particles of smaller mass acquire a higher mean velocity than those of larger mass, and this enables them to rebound to sufficient height to escape over the edge of the beaker. If this explanation is correct, then it would suggest a close analogy between the behaviour of a mixture of gases of different molecular weight and a powdered material having a wide range of particle size.

Air-Flux Sensitivity of the Pulses of the Negative Point to Plane Corona in Air at Atmospheric Pressure

THE negative point to plane corona, glowing at atmospheric pressure in air, may be looked upon as a result of a large number of self-quenched electron avalanches per unit time. The effect of self-quenching occurs only in the case when an electronegative gas component is present and is due to a cloud of negative ions influencing strongly the electric field in the vicinity of the sharp end of the cathode[1]. When a sufficiently high potential difference exists between the cathode and a flat anode, the current pulses follow each other with a high frequency and the negative ions strongly decrease the amplitudes of the voltage pulses occurring on the resistance R placed in series with the point cathode[2,3]. For a sufficiently high frequency of the electron avalanches (increases with the applied voltage), the following approximation should describe the change of the amplitude of the voltage pulses due to the negative-ion concentration or pulse-frequency:

$$A \pm \Delta A \sim \frac{1}{N \pm \Delta N} \sim \frac{1}{K \pm \Delta K}$$

for $N_{V_1} < N < N_{V_2}$ and $V_1 < V_2$.

Here A is the amplitude of the voltage pulses, N their frequency, V_1 and V_2 are the values of the voltage, N_{V_1}, N_{V_2} are the frequencies of the pulses at certain critical voltages V_1, V_2. K is the negative-ion concentration in the vicinity of the cathode when the frequency of the pulses is N.

The values of N or K may be changed by: (*a*) blowing away a number of negative ions per unit time resulting in a decrease $(-\Delta K)$ of K; (*b*) cooling the vicinity of the sharp end of the cathode resulting in a decrease $(-\Delta N)$ of the number of primary electrons N initiating the avalanches.

All this suggests in general that a change of N or K for a constant voltage V $(V_1 < V < V_2)$ may be measured by the intermediary of the amplitude change of the pulses. This may be done by discrimina-

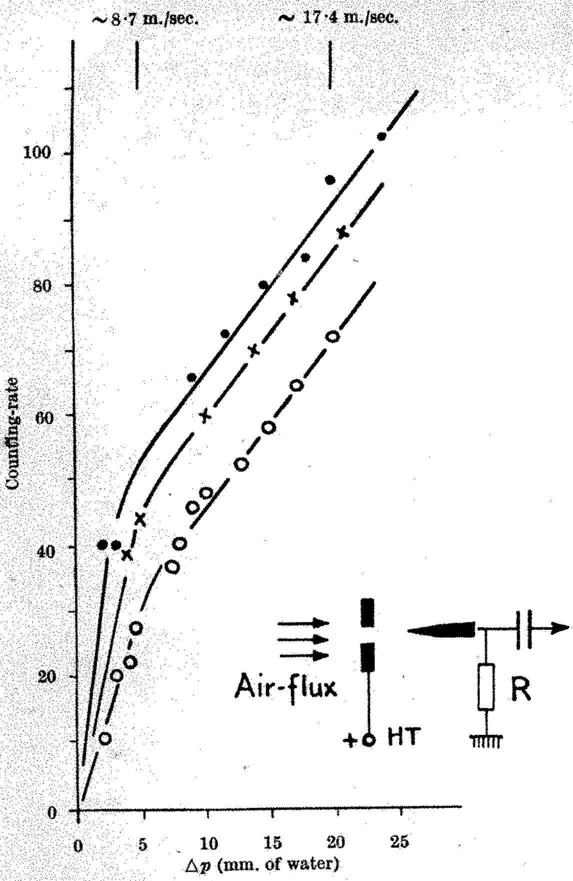

Fig. 1. The graphs show, in arbitrary units, the dependence of the counting-rate of the registered pulses, versus the air velocity, measured with a Prandlt's tube. The air velocity is given as a measure of the pressure difference: $\Delta p = \frac{\rho}{2} v^2$. Each curve was measured at different discrimination. V = constant

tion of those pulses the amplitudes of which are smaller than a certain preferred and fixed value.

To test the air-flux sensitivity, an atmospheric Geiger counter was used. The counter consisted of a sharp cathode and a metal face ring and was used together with a high-voltage stabilizer, a cathode follower, a discriminator unit and a counting-rate meter. The air-flux influence on the pulse amplitudes could be observed on the oscilloscope screen also. When an appropriate voltage V ($V_1 < V < V_2$) is put on the counter, a light phenomenon of the negative point corona can be observed at the sharp end of the cathode. On the oscilloscope screen one may see a large number of single pulses. The amplitude of these pulses is very small. When discriminating these pulses the counting-rate meter shows no counting-rate at all; but if an air stream is directed into the discharge space the amplitude of some of the pulses increases. The counting-rate meter registers now the increased pulses.

Fig. 1 shows some graphs of preliminary observations. Each curve is measured for a certain constant discriminating factor of the pulse discriminator and for a constant voltage. These graphs show the similar character of the curves. The preliminary oscilloscope observations show furthermore that there exists an inversion-like voltage, similar to that described by Mohanty[4] in the case of the Joshi effect.

I wish to thank Prof. J. Nikliborc for his kind interest in this problem.

Motion of Sporadic-E Patches determined from High-Frequency Backscatter Records

New evidence of the motion of 'sporadic-E' ionization has been obtained at Stanford University from records of ionospheric sounding equipment which displays ground (or sea) backscatter as mirrored in ionospheric layers or reflecting clouds. Sporadic-E patches of relatively limited geographical extent (order of 10,000 sq. km.) often appear on the records of this apparatus, and their growth and motion can in some cases be followed. Whether this motion is due to physical translation of the ionized material (as by winds) or to some other cause such as motion of an ionizing agency is not known; however, it is of interest to compare observations made by this relatively new technique with earlier ones made by other means.

The backscatter[1-3] in use at Stanford employs a rotating unidirectional beam antenna of relatively low directivity, and a plan position (PPI) display. A 2-millisecond pulse having a peak power of one kilowatt is radiated at 17·3 and 30·66 Mc./s. The antenna rotates once per minute, and a photographic record is made of each scan in azimuth. The equipment has been operated virtually continuously since September 1952.

Detailed observation of E_s clouds or patches showed that the number which can be clearly distinguished as separate events is approximately 2,700 in the three-year period. Duration of the individual patches varied from a few minutes to a maximum of 10·5 hr., with a mean value of 3 hr. Every patch was examined for indications of motion. If during a period of one half-hour a given patch did not dissolve or become mingled with other activity so that it could no longer be studied as a unit, it was chosen for plotting. The centroid of the patch,

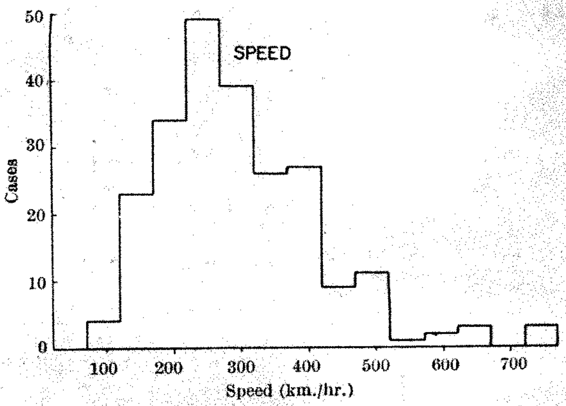

Fig. 1. Speed distribution of sporadic-E patches observed on high-frequency backscatter equipment

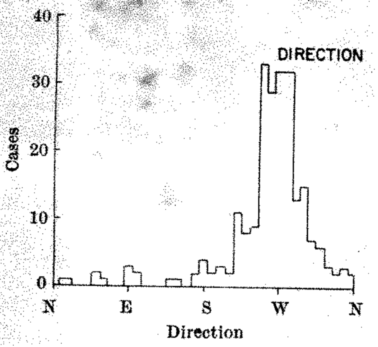

Fig. 2. Direction distribution of sporadic-E patches observed on high-frequency backscatter equipment

defined as the mean range and the mean angular position in azimuth, was plotted until the patch either moved out of range or was otherwise lost. A total of some 264 such tracks were studied and speed and direction information derived.

These results are shown in Figs. 1 and 2. The speed distribution has a peak at 250 km./hr.; but a few very high-speed cases raise the mean value to 300 km./hr. In only nine cases out of 264 were speeds greater than 550 km./hr. recorded. Direction is predominantly toward the west, and in 80 per cent of the cases it was within 45° due west. It is interesting to note that the mean speed is approximately one-fourth of the speed of the subsolar point at this latitude, and the average direction of patch motion is the same as that of the subsolar point.

Apparent speed of drift of these patches is in good agreement with that of ionospheric winds, as determined by the meteor trail drift method[7-9], and of E_s motion, as measured by the fading method[6,10]. However, the predominant direction of motion of the sporadic-E patches in this study does not agree with the predominant directions of motions determined by the other methods. Moreover, the present work brought to light no diurnal changes in the direction of apparent motion as have previously been reported.

Ferrell and Gerson have previously deduced sporadic-E cloud drift by a method somewhat analogous to the present one, utilizing radio amateur transmissions in the 50-Mc./s. band[4,5]. While the speeds which they reported were in rough agreement with those of the present study, the directions reported were variable and showed no particular tendency to favour the west. The number of patches observed in this study is far larger than the number reported by Ferrell and Gerson.

Supporting evidence for the reality of the patch position and time measurement was obtained with the aid of the C-3 vertical incidence ionospheric sounder at Stanford University. Forty-one of the tracks plotted had directions which carried them directly overhead at Stanford. From the trails, predictions of arrival time overhead were made and verified by searching for a peak in the sporadic-E penetration frequency, as indicated on the vertical sounder records for the predicted time. The agreement was close in 90 per cent of the cases. In only two cases did the patch fail to appear overhead. In both these instances the patches were receding from the sounder and extrapolation backwards in time was required. These patches, accordingly, may have been formed at times later than their calculated time of appearance overhead.

Further details will be found in a paper now being prepared for publication.

High-Energy Particles in Solar Flares

AT a recent lecture delivered at Harwell, Dr. I. V. Kurchatov gave details of Russian experiments with high current-density gas discharges. One interesting phenomenon that was observed concerned the production of high-energy particles in the discharge, possessing energies greatly in excess of those that could be attributed to the Maxwellian distribution at the temperatures reached in the spark, and also greatly in excess of the electron-energy corresponding to the potential difference across the spark gap. This effect could be observed in deuterium through the production of neutrons and gamma-rays. The onset of this phenomenon was always clearly related to a certain behaviour of the spark, namely, to the second constriction that occurred. It must therefore be supposed that in the complicated electrodynamical processes that occur in sparks that become constricted in their own magnetic field, there occurs a mechanism for accelerating a small fraction of the particles to high energies. This can perhaps be understood in terms of multiple reflexions of ions in the interior of a rapidly converging cylindrical magnetic shock wave.

The interpretation of solar flares is not yet clear. The effect could well be interpreted as an electrical discharge; but in a gas already highly ionized before the discharge, it is necessary to find a reason for the sudden onset of the phenomenon. It could be that electric currents evenly distributed through large volumes normally flow in the vicinity of changing sunspots; but that in circumstances when the current density exceeds a certain value, an instability occurs causing the currents to become constricted along one or several lines due to their own magnetic fields (the 'pinch' effect).

High-energy particles are produced in solar flares, as is clear from certain radio observations and from the occurrence of associated cosmic-ray effects. If the interpretation of a flare given here is correct, the Russian experiments would seem to provide a laboratory analogy for this effect which will greatly facilitate further analysis.

The *d*-Band Character of Metals and the Rate and Mechanism of the Electrolytic Hydrogen Evolution Reaction

It is known empirically[1] that for the hydrogen evolution reaction, log i_0 (where i_0, the exchange current density, is directly proportional to the rate constant of the reaction) increases linearly with increase of φ, the thermionic work function of the electrode substrate, for most metals, but may decrease with increase of φ for mercury, thallium and lead. The work function is eliminated in the potential terms governing the rate of hydrogen evolution in an actual cell. The origin of the dependence of rate constant upon φ must therefore be sought in the relation to φ of some other parameter upon which the rate of evolution of hydrogen depends.

It is simple to show[2,3] that if the reaction:

$$H_3O\cdot + e_0^- \rightarrow M\text{H}$$

(M = metal substrate) controls the overall rate of the hydrogen evolution reaction, log i_0 should increase approximately linearly with $\Delta H_{\text{ads.H}}$, the heat of adsorption of hydrogen on the metal. $\Delta H_{\text{ads.H}}$ is known experimentally for a number of metals. It is of interest here, however, to relate $\Delta H_{\text{ads.H}}$ to φ through the equation due to Pauling for the relation of the heat of formation ($-D_{M\text{H}}$) of the metal hydride, MH, to the heats of dissociation of MM and HH, and the electronegativities of M and H, that is, $-D_{M\text{H}} \neq \Delta H_{\text{ads.H}}$, but will differ from it essentially only by the image potential at the $M-$H interface; this potential is not primarily dependent upon φ. $-\Delta H_{\text{ads.H}} - D_{M\text{H}}$ is found to be 10–15 kcal. mole^{-1} for a series of metals (Fig. 1); the image potential[4] is approximately −15 kcal. mole^{-1}.

$$D_{M\text{H}} = \tfrac{1}{2}(D_{MM} + D_{\text{HH}}) + 23{\cdot}06\,(X_M - X_{\text{H}})^2 \quad (1)$$

In (1), D_{MM} and X_M can be related to φ by the equations[5]

$$D_{MM} = 23{\cdot}06 \times 0{\cdot}6\,\varphi/0{\cdot}52\,n \quad (2)$$

and

$$X_M = 0{\cdot}355\,\varphi. \quad (3)$$

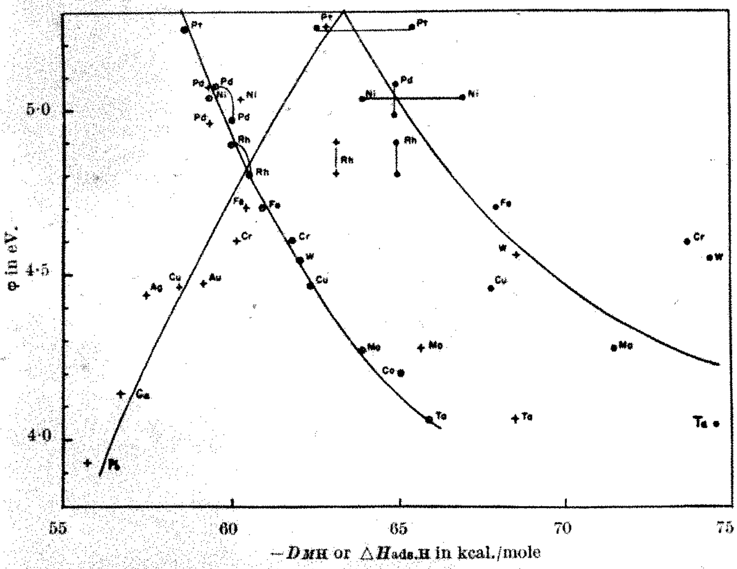

Fig. 1. Dependence of metal-H interaction energy upon electron work function. +—+, Values of $-D_{M\text{H}}$ calculated from equation (1) neglecting X_M. ●—●, Values of $-D_{M\text{H}}$ calculated from (1) including X_M as $f(\varphi)$. ⊙—⊙, Experimental values of $\Delta H_{\text{ads.H}}$ (refs. 5 and 7). Values of φ are mainly from the post-1950 literature and were chosen critically with regard to use of rigorous purification techniques

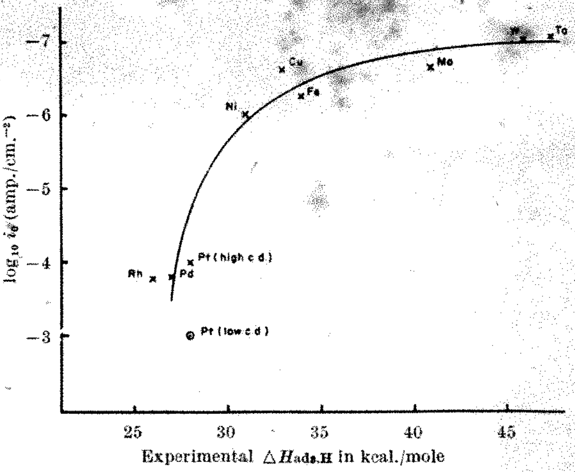

Fig. 2. Dependence of log i_0 upon $\Delta H_{\text{ads.H}}$ (both parameters measured under conditions of highest purification of solutions and surfaces)

If the electronegativity term in (1) is neglected (cf. ref. 6), the relation of $D_{M\text{H}}$ (or $\Delta H_{\text{ads.H}}$) to φ is as shown in Fig. 1 and, on this basis, it follows that $\Delta H_{\text{ads.H}}$ increases with increase of φ, so that if proton transfer determined the rate, log i_0 would increase with increasing φ, as is found empirically[1]. The conclusion from this kind of relationship that the rate-determining step for many metals was proton transfer was recently drawn by Ruëtschi and Delahay[6] in an application of the potential energy curve theory of Parsons and Bockris. If, however, the electronegativity term is included in equation 1, the relation of $D_{M\text{H}}$ (or $\Delta H_{\text{ads.H}}$) to φ is as shown in the second curve in Fig. 1. The trend is in the opposite direction to that obtained when the electronegativity term in (1) is neglected[6] and now agrees with the trend of experimental $\Delta H_{\text{ads.H}}$ values with φ. It follows that the experimentally observed plot of log i_0 against φ indicates that the rate constant of the hydrogen evolution reaction for many metals decreases with increase of the numerical magnitude of $D_{M\text{H}}$ (or $\Delta H_{\text{ads.H}}$); that is, behaves in the opposite sense to that theoretically expected if proton transfer determined the rate, and to that concluded by Delahay and Ruëtschi, who neglected the effect of electronegativity. The latter term in equation (1) contributes 0 and 20 per cent of the value of $D_{M\text{H}}$, depending on the metal. It is, however, an important term leading to variation of $D_{M\text{H}}$ with the metal.

It follows that for the large group of metals referred to (those for which log i_0 increases linearly with φ, namely, copper, silver, gold, molybdenum, tungsten, iron, nickel, cadmium, gallium, aluminium, rhodium, palladium, platinum) a desorption of hydrogen atoms must occur in formation of the activated complex in the rate-determining step. Such a rate-determining step is:

$$H_3O\cdot + M\text{H} + e_0^- \rightarrow H_2 + H_2O + M \quad (4)$$

the so-called 'electrochemical mechanism'[1], and the kinetic parameters characteristic of this reaction as the rate-determining step have in fact been observed[1,5] for a number of the above metals in acid solutions. For these metals of intermediate hydrogen overpotential, therefore, equation (4) determines the rate, whereas for the metals mercury, lead and thallium, it appears that the proton discharge is the rate-determining reaction (cf. ref. 1), and at platinum the desorption by recombination of adsorbed hydrogen atoms determines the rate.

The relation of i_0 to the structure of the metallic substrate arises as follows. It has been recently established[7] that decrease of d-character is associated with increased heat of adsorption of hydrogen. The exchange current density would therefore be expected to decrease with decreasing d-character, as is experimentally verified[5]. The relationship to φ arises similarly, as φ increases with the amount of d-character[5], owing to the lower energy of electrons when more are paired as the d-band becomes more filled.

Detection of Free Radicals in Sodium Dithionite by Paramagnetic Resonance

It has been shown[1] that the photochemical oxidation of a bound oxalate ion leads to the formation of a free radical (assumed to be $C_2O_4^-$ or CO_2^-). In view of the formal analogy between the oxalate ion, $C_2O_4^{2-}$, and the dithionite ion, $S_2O_4^{2-}$, and the possibility of their undergoing oxidation by similar mechanisms[2], we have investigated the possibility of producing the corresponding free radical from the dithionite ion. The paramagnetic resonance apparatus was similar to that previously described[1]. All measurements of paramagnetic resonance absorption were made at liquid-oxygen temperature with the samples sealed in thin-walled evacuated glass tubes.

Samples of anhydrous sodium dithionite showed a weak paramagnetic resonance absorption having a g-value of $2{\cdot}01 \pm 0{\cdot}01$ and width of 12 ± 3 gauss, suggesting that it was due to a free radical. This weak absorption could still be detected after pumping under high vacuum at a temperature of 60–70° C. Treatment of the crystals *in vacuo* with a small quantity of degassed water caused an increase in the free radical content which grew during 1 hr. at room temperature. When sufficient water was added to dissolve the crystals completely at room temperature, and the solution was again frozen at liquid-oxygen temperature, no free-radical absorption could be detected. Part of the water was then evaporated into the side-arm until crystals separated. On freezing in liquid oxygen, a free-radical signal was again observed. On admittance of air the free radicals did not disappear until the mixture had stood for some time. The free-radical content of the anhydrous dithionite was also found to increase when wetted with ethyl alcohol.

The free radicals observed in the wetted anhydrous crystals were found to be quite stable in the absence of air and were observed after storage for several days at room temperature. The free-radical content was estimated to be approximately 6×10^{17} per gm., corresponding to the dissociation of about 0·01 per cent of the dithionite ions. This may not, however, represent the total quantity of free radicals present, owing to possible broadening of the absorption band in solution. It is not yet clear, therefore, whether the radicals are present only in the crystals or whether they are also present in the aqueous solution. It is possible that the radicals are stabilized by adsorption on the crystal surfaces[3]. Certainly no signal has so far been detected in those tests in which the crystals had completely dissolved.

The two most probable formulæ which have been suggested for the dithionite ion are $[O_2S.SO_2]^{2-}$ and $[OS.O.SO_2]^{2-}$. The second (mixed anhydride) formula is supported by chemical evidence[4]. Bassett and Durrant[4] postulate the existence of two forms of the free acid, one corresponding to each of these ionic structures. The first form has a similar structure to that of the oxalate ion. From the results of an X-ray analysis of crystals of anhydrous sodium dithionite, Dunitz[5] concludes that the dithionite ion can be regarded as a pair of SO_2^- units linked by a weak S—S bond, and he suggests that the SO_2^- radical occurs at least as a transitory species. The existence of SO_2^- radicals in aqueous solutions of dithionite has already been suggested[6] to account for the polarographic behaviour of sodium dithionite in neutral or alkaline medium. The SO_2^- radical would be expected to act as a reducing agent, analogous to the oxalate radical, owing to the reaction $SO_2^- \rightarrow SO_2 + e$, as suggested by Dunitz[5].

We wish to thank Dr. W. Furness, of Messrs. Brotherton, Ltd., for the sample of anhydrous sodium dithionite.

Moult Adaptation in Relation to Long-Distance Migration

Marshall and Serventy[1] have recently directed attention to moult adaptation in the short-tailed petrel, *Puffinus tenuirostris*, of Tasmanian waters. In this species post-nuptial head and body moult takes place in the breeding quarters while moult of tail- and wing-feathers is postponed until the bird has arrived at its northern non-breeding quarters. From this the authors decide that "from the . . . data there emerges clear evidence of the evolution of a moult adaptation related to the migratory requirements of species that undergo a long post-nuptial migratory movement". That moult adaptation in relation to long-distance migration need not be a general phenomenon, and probably has only taken place in certain families of birds, is indicated by the following observations on two species of long-distance passerine migrants. In April 1953 a large number of swallows, chiefly consisting of the European swallow, *Hirundo rustica*, and the European house martin, *Delichon urbica*, perished in the neighbourhood of Cape Town, due to a short spell of adverse weather conditions. Of the thirty-five *H. rustica* examined, 99·1 per cent showed moulting flight-feathers, 65·7 per cent had moulting tail-feathers and 8·6 per cent had moulting body- and head-feathers. Of fifty-two *D. urbica*, 40·4 per cent had moulting wing-feathers, 75 per cent moulting tail-feathers and 94·2 per cent moulting body- and head-feathers[2].

It is in April that these swallows leave southern Africa on their long-distance flight to the northern breeding quarters. Moulting flight- and tail-feathers at this time must be a disadvantage to these birds. The above data show that the moult which these swallows undergo in their wintering quarter sets in late and is continuous with no hiatus between the moulting of body- and head-feathers and the wing- and tail-feathers. Swallows are also very much dependent on their wings just as petrels are. Still, moult adaptation in relation to long-distance migration seems to have taken place in one but not in the other.

Injury from the Decompression Component of an Air-Blast Wave

PREVIOUS experiments have shown that about 80 per cent mortality is to be expected when 60-day old mice are explosively decompressed, in a matter of 30 m.sec., from a pressure of 80 lb. per sq. in. above atmospheric. Since the positive phase of an air blast wave is characterized by a shock front followed by a rapid drop in pressure comparable to explosive decompression, it was thought of interest to investigate the lethal effect of this component of the blast wave. Accordingly, mice were subjected to 80 lb. per sq. in. over-pressure for varying durations of time and then explosively decompressed. No lethal effect was observed until the mice had been under pressure for times longer than 100 m.sec. At 1 second the mortality had only risen to about 12 per cent, as compared with the control data on 80 per cent mortality which was obtained when the mice were under pressure for a matter of 1 min. It is therefore concluded that the explosive decompression component of the blast wave has no lethal effect *per se*. Details of this work will be reported later.

Spike Potentials produced by the Sea Lamprey (*Petromyzon marinus*) in the Water surrounding the Head Region

UNDER the auspices of the Fisheries Research Board of Canada an investigation was started recently in this laboratory on hearing in the sea lamprey. During preliminary observations, adult *Petromyzon marinus* were placed in rigid 'Lucite' cylinders of 1½ in. inner diameter. A row of silver electrodes had been placed in the wall of the tube at 1-in. intervals along a straight longitudinal line. Each of the electrodes could be connected individually with a d.c.-fed pre-amplifier. The last electrode in the row, located beyond the tail of the animal, served as reference electrode. The tube, filled with fresh water and containing the animal, was kept in a Faraday cage together with the pre-amplifier. The output of the amplifier was connected with a cathode ray oscilloscope. In the water surrounding the head region spike potentials were recorded from electrodes 15–20 mm. away from the animal's surface. Fig. 1 represents a recording from an electrode located immediately above the left eye of the animal. The triphasic spike has a duration of about 20 m.sec. and a potential of 200 μV.; the positive third phase has a potential of 30 μV. and lasts about 15 m.sec. Successive recordings from electrodes headwards or tailwards demonstrated that the highest potentials in the water were towards the anterior extremity of the animal, that is, surrounding the region of the head anterior to the eyes. The values of the potentials decreased rapidly posteriorly to the eyes and no spikes could be recorded from electrodes beyond a distance of 2–3 in. from the eyes towards the tail of the animal. The electrical field was therefore confined to the anterior end of the body.

By recording with continuously moving film and using single sweeps, the frequency of the spike potentials was determined. Fig. 2 represents a short section of such a film. The time scale is 0·1 sec. The spikes on this film recur with a frequency of 0·4 sec., but under different experimental conditions this frequency changed. It was established that the recurrence of the spikes is synchronous with the externally visible respiratory movements of the gill

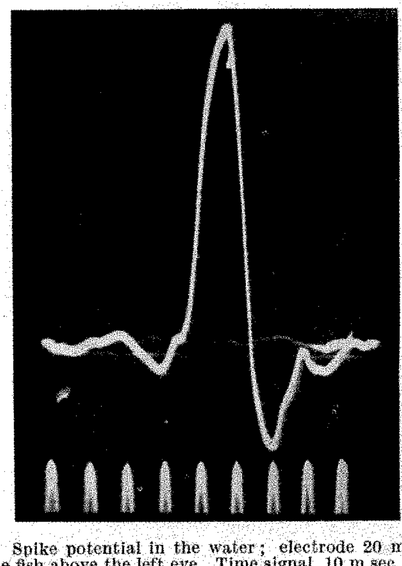

Fig. 1. Spike potential in the water; electrode 20 mm. away from the fish above the left eye. Time signal, 10 m.sec.; 200 V.

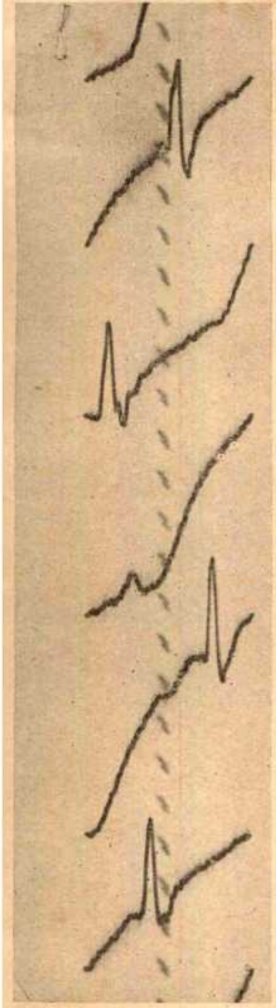

Fig. 2. Spike potentials recorded in the water surrounding the head of the sea lamprey. Time signal, 100 m.sec.

openings. This synchronization was determined by amplifying the spike potential sufficiently to light a 6-V. bulb and by making a motion picture of the gill movements and of the flashing bulb, held in the same photographic field. The spike potentials occur a fraction of a second before the onset of the closing movement of the gill openings. Fig. 3 represents a photograph of the head region of the sea lamprey, made by means of a photographic flash bulb fired by the amplified spike potential. The picture was taken with open camera shutter in complete darkness but for the firing period of the flash. It therefore represents the exact position of the gill openings at the moment the spike potential occurred. In Fig. 3 the gill openings are about to be constricted.

Detailed measurements of the electrical field were made in tubes of a more refined construction, and a number of recordings were made of potentials generated by lampreys in larger containers. Data obtained by these observations will be reported elsewhere.

At the present time, two main aspects of the observations made by us are being studied. (1) What is the source of the potentials recorded and (2) what are their functions, if any ? The source must be a powerful one since a potential of 200–300 μV., 20 mm. away from the animal, in fresh water, represents a considerable amount of energy at the source. In order to allow for the emission of this electrical energy into the water surrounding the head of the animal, a special organ or 'window' must be present in the skin, connecting the source with the outside medium. Preliminary experiments were made in order to determine the nature of this source, which may be the action potential of nerve or muscle. The shape of the spike potential represented in Fig. 1 resembles that of a nerve action potential in a conducting medium. Animals injected with strychnine sulphate, however, did not emit spikes of higher potential than non-injected animals. Treatment with curare and cocaine did not give conclusive information, and further experiments are now in progress to determine the source of the electrical field.

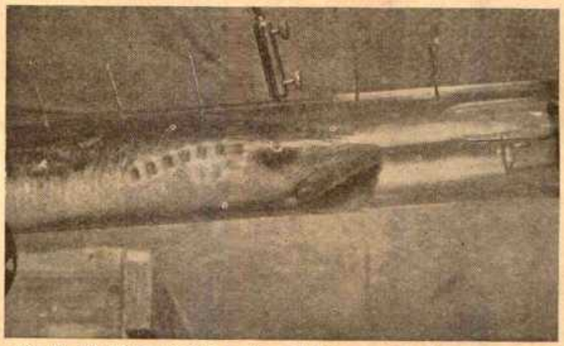

Fig. 3. Position of gill openings at the moment of occurrence of the spike potential in the water. Photoflash was fired by the amplified spike potential

As to the functions of these potentials in the life of the sea lamprey, it must be stated that the frequency of the spikes excludes their usefulness for 'radar' orientation. It is, however, very well possible that the lamprey is able to perceive changes in the electrical field surrounding its head and can thus sense the approximation of solid objects such as prey. In this connexion it may be pointed out that the lamprey's eyesight is poor and that the behaviour of lampreys in aquaria indicates that prey fish are attacked only when they are within a distance of a few inches from the lampreys.

Counter-Streaming Centrifugation of Bull Spermatozoa

PRELIMINARY experiments aiming at a separation of bull spermatozoa determining male and female sex were undertaken with a counter-streaming centrifuge[1]. Originally it was assumed that the female-determining spermatozoa, carrying a large X-chromosome[2], should have a greater volume or—the volumes being equal—a higher density than the male-determining ones, carrying a small Y-chromosome[2]. Later it was, however, demonstrated that the density of bull spermatozoa increases in the course of their physiological maturation[3]. This change in density is of such an order of magnitude that it totally obscures the difference in sedimentation-rate due possibly to the difference in volume between the sex chromosomes. Differences in sedimentation-rate might further be caused by as yet unknown differences in shape between the two kinds of spermatozoa.

In all experiments a slightly modified phosphate-buffer of Phillips and Spitzer[4] was used as suspension liquid. The separations were finished within thirty minutes. During this time the temperature of the introduced suspension liquid was lowered from 20° to 12° C. So far, only the fraction of spermatozoa retained in the centrifuge, representing a selection of larger and/or denser ones, has been used for inseminations.

In one experimental series the centrifuge was run at 1,200 r.p.m. and the rate of flow (12 ml./min.) of the suspension liquid was so adjusted as to make the retained fraction about half the introduced material. Of the 376 inseminated cows 187 became pregnant, corresponding to a fertility of 49·7 per cent. The mean fertility at the Artificial Insemination Station during the same time was 55 per cent. The sex of the calves was reported. There was no significant deviation of the sex-rate from that of the corresponding control group.

In another series the centrifuge was run at 1,100 r.p.m., and the rate of flow (16 ml./min.) of the suspension liquid was so high that only one-twentieth to one-fifteenth of the spermatozoa were retained in the centrifuge. They showed very low motility (over-ripeness[3] ?). For this reason, and on account of the scantiness of spermatozoa, only 24 inseminations were performed with this material. Of the cows 12 became pregnant, all belonging to different herds. One cow had to be slaughtered later. The 11 calves were all males. In the corresponding control group of 9 calves, 3 were males and 6 females.

The last series of experiments is being repeated.

I am very much indebted to the Artificial Insemination Association of Enköping for allowing me to perform these experiments, and to the chief veterinarian, Dr. T. Svensson, and to Dr. K. Idla for most valuable co-operation. The counter-streaming centrifuge was run by Mr. P.-Å. Lindström. Financial support from Ely Lilly and Co. is gratefully acknowledged.

Blood-Histamine and Tissue-cell Anoxia in Mental Disease

WORK in our laboratories, *inter alia*, has been concerned for some years with the aberrant morphology[1] and physiological responses[2–4] of the peripheral capillary vascular system of patients with schizophrenia and other mental disturbances. More recently, we have been concerned with the effects of these responses of the minute vasculature on the oxygenation of the adjacent tissue cells. In brief, we have found that, under conditions of increased capillary pressure, lessened local blood-oxygen saturation and capillary corpuscular flow (often with intravascular erythrocytic agglutination), hydration, swelling, vacuolization, granularity and other degenerative changes reminiscent of cellular cloudy swelling occur progressively in the intervascular tissue substance[5]. These changes reverse themselves when the vascular conditions seemingly causing them also suffer a reversal. Although these changes have been observed from time to time in healthy subjects, they are much more characteristically seen, and for much longer periods of time, in psychiatric patients, and especially in psychotics. Also, these vascular and cellular responses seem to coincide in time with significant happenings in the mental state of the patients and the dynamic variations occurring in their state of consciousness (for example, a worsening of the pathophysiology takes place when hallucinations are experienced[6] or when a myoclonic seizure[7] occurs in an epileptic, while an improvement in these reactions coincides with recovery or subsidence of these events).

Our interest in the mechanism whereby the cell could conceivably be affected by a diminution in the supply of molecular oxygen in the capillaries led to a study of the histamine metabolism of psychiatric patients. Using the Lowry *et al.*[8] column chromatographic microchemical method of estimating blood histamine (modified by trebling the concentration of DNFB per aliquot) and 5-ml. blood samples obtained by venupuncture, we investigated both mentally healthy and mentally sick populations all in the non-fasting state. In the former ($N = 12$) we found a mean blood histamine-level of 88·86γ per litre ($s = 27{\cdot}43$), that is, very close to the mean of 82·0γ per litre for 'true' histamine reported by Lowry *et al.* and the figure of 86γ per litre obtained by Valentine *et al.*[9] from 16 non-fasting healthy subjects using Code's[10] modification of the original Barsoum and Gaddum[11] bioassay technique. In the latter population the mean levels were invariably greater, those for schizophrenia ($N = 29$) being 106·38γ ($s = 24{\cdot}84$) and contrasting with those for epilepsy ($N = 5$) at 139·42γ per litre ($s = 24{\cdot}57$), while those for other psychiatric conditions ($N_T = 66$) lay between these two values. An analysis of variance showed the differences between the means to be significant ($P = 0{\cdot}01$) and no significance could be attached to the possible variables of age and sex.

If these results are confirmed, their repercussions on stress-theory and on the role of histamine metabolism in this theory will be considerable; as they stand they strengthen the growing evidence favouring the relationship between tissue anoxia, mental disease and histamine release. We are currently engaged in extending our experiments in a longitudinal fashion in an endeavour kinetically to correlate the precise vascular and tissue events in circumstances of changing concentrations of blood histamine. The results contained in this communication will be published in greater detail in specialist journals elsewhere.

Detection of Xanthine Dehydrogenase Activity in Soluble Proteins of Rat Liver separated by Paper Electrophoresis

IT has been shown by paper electrophoresis that xanthine dehydrogenase activity is bound to the globulin fractions of rat serum[1]. Using differential centrifugation, it was demonstrated that xanthine oxidase and xanthine dehydrogenase activities are present in the supernatant fluid corresponding to the 'cell sap' containing the soluble proteins of the rat liver[2].

A large number of proteins are present in the 'cell sap' fraction of the rat liver, and they have recently been separated by paper electrophoresis[3]. We were

Table 1. Protein and Xanthine Dehydrogenase Activity of Ten Rat Liver Supernatant Fluids

* $S.d. = \sqrt{\Sigma(d^2)/(n-1)}$

interested to know which of these fractions showed xanthine dehydrogenase activity.

Wistar white adult male rats weighing 150–200 gm. were used throughout the present work. The rats were killed by decapitation and the livers removed immediately after death and kept in crushed ice until fractionation. The differential centrifugation was carried out according to the technique of Hogeboom, Schneider and Pallade[4], as previously described[2]. The tissue homogenate was prepared by extracting the soluble proteins with 1·5 vol. of cold 0·25 *M* sucrose solution in a Potter–Elvehjem glass homogenizer. After the differential centrifugation the soluble fraction was separated and 0·05 ml. was applied to Whatman No. 3 filter paper strips for the electrophoretic separation. We have used an *M*/15 phosphate buffer *p*H 7·4 instead of borate buffer used by Adjutantis[3] since the borate was shown to inhibit the xanthine dehydrogenase activity[5]. The electrophoresis proceeded for 18 hr. using a potential difference of 250 V. which should give a current of 4–4·5 mA. in our experimental conditions.

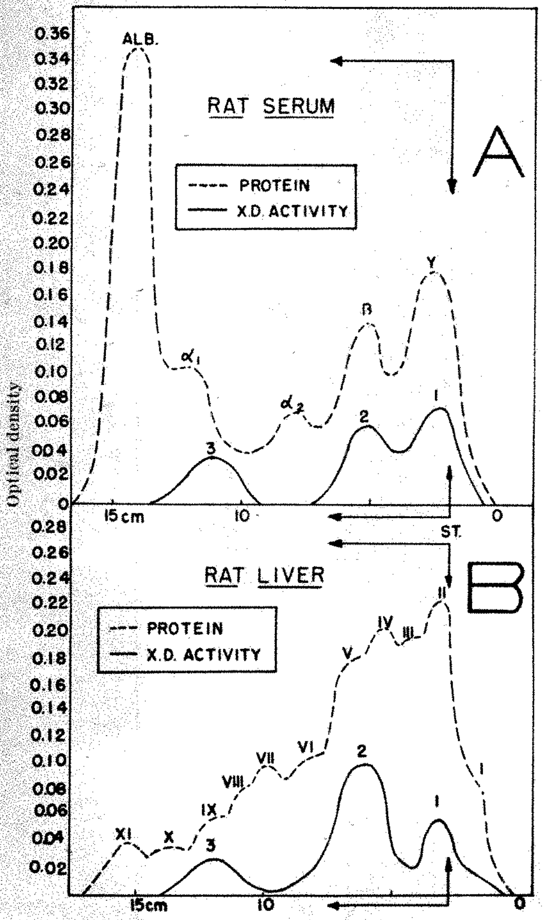

Fig. 1. Paper electrophoresis of rat serum (*A*) and liver supernatant fluid (*B*) on Whatman No. 3 filter paper using phosphate buffer *p*H 7·4. Arrows indicate site of application of samples and direction of run

Nitrogen determinations were performed on the soluble fraction of rat liver, as previously mentioned[2], to control the fractionation. The xanthine dehydrogenase activity was determined in the paper electropherograms, as shown for rat serum[1], by the reduction of the triphenyltetrazolium chloride to formazan, according to the method of Villela[6]. Control blanks without substrate were made simultaneously.

The experiments were performed on ten rats, and the results of the nitrogen determinations (1,031 ± 89 μgm. nitrogen per 100 mgm. fresh liver or its equivalent) showed the homogeneity of each sample, indicating that only proteins of the supernatant were present.

Eleven components were found by paper electrophoresis to be present in the soluble-protein fractions. The relative amount of each component was determined by planimetry of the areas according to the method of Pedersen[7] The results, together with the relative quantity (percentage) of xanthine dehydrogenase activity found for each fraction, are shown in Table 1 (mean of ten experiments).

The distribution of xanthine dehydrogenase activity in the protein fractions can be clearly seen in Fig. 1*B*. Three peaks are related to the protein fractions II, V and IX, and the values obtained from the calculated area are shown in Table 1.

In Figs. 1*A* and *B* the proteins and xanthine dehydrogenase activity diagrams of the liver and serum are shown for comparison. The protein fractions of rat liver and serum containing xanthine dehydrogenase activity give the same mobility-rate. Since it was also shown that xanthine dehydrogenase of rat liver and serum are both strongly influenced by carbon tetrachloride *in vivo* and *in vitro*[8,9], these results suggest that the xanthine dehydrogenase of liver and serum are probably similar.

This investigation was supported in part by grants from the Conselho Nacional de Pesquisas (E. Mitidieri) and from the C.A.P.E.S. (L. P. Ribeiro).

Sodium and Potassium Content of Isolated Nuclei

It is well known that the concentration of sodium is low and that of potassium high in the intracellular space of most mammalian tissues. Nevertheless, an appreciable amount of each has been found in preparations of mitochondria isolated by differential centrifugation from homogenates of various tissues, particularly liver[1-4] and kidney[5]. The purpose of the present communication is to report on the association of sodium with another cellular component, the nucleus.

Nuclei prepared from calf thymus cells in 0·25 *M* sucrose–0·003 *M* calcium chloride solution[6,7], nuclei from calf thymus, liver and kidney isolated in non-aqueous media[8] and whole tissues similarly treated were kindly provided by Drs. V. G. Allfrey, A. E. Mirsky and S. Osawa, to whom we are greatly indebted. The sodium and potassium content of the isolated nuclei and whole tissues was determined by internal standard flame photometry after digestion with nitric acid.

Thymus nuclei prepared in non-aqueous media contained 238 μequiv. of sodium and 661 μequiv. potassium per gm. dry weight. Since the water content of the nuclei was 83 per cent, the sodium content was calculated to be 40 μequiv. and the potassium content 112 μequiv. per gm. wet weight. The sodium and potassium content of fresh thymus tissue averaged 38 ± 1·5 (s.e.) and 116 ± 1·5 (s.e.) μequiv. per gm. wet weight, respectively, and corresponded closely to the values of 43 μequiv. of sodium and 107 μequiv. of potassium per gm. wet weight found for the whole ground tissue after treatment with non-aqueous media. The similarity of the sodium and potassium concentration in the fresh and treated tissue suggests that there was no significant loss of sodium and potassium from the tissues into the media (petroleum ether, cyclohexane and carbon tetrachloride) during the non-aqueous procedures used for the nuclei.

The electrolyte content of nuclei isolated in sucrose solution was considerably lower, averaging 15 ± 0·8 (s.e.) μequiv. of sodium and 42 ± 2·1 (s.e.) μequiv. of potassium per gm. wet weight (42 experiments). In Table 1 these data are expressed as μequiv. per gm. dry weight. The sodium content of the nuclei isolated in sucrose averaged 87 ± 4·8 μequiv. per gm. dry weight with a range of 40–157 μequiv. per gm. dry weight; the potassium content averaged 244 ± 12·2 μequiv. per gm. dry weight with a range of 141–481 μequiv. per gm. dry weight. If the values obtained for nuclei isolated in non-aqueous media represent the natural cation content of the nucleus, an average of 62·5 per cent (range 17–73 per cent) of the original sodium and potassium is lost from the nucleus by the repeated washings with sucrose solution during the preparation.

The sodium and potassium content of liver and kidney nuclei isolated in non-aqueous media also proved to be approximately the same as that of the whole tissue (Table 1).

Table 1. THE SODIUM AND POTASSIUM CONTENT OF TISSUES AND NUCLEI (μEQUIV. PER GM. DRY WEIGHT)

	Na	K	Na/K
Isolated in non-aqueous media :			
Calf thymus : Whole tissue	257	627	0·41
Nucleus	245	639	0·38
	230	683	0·34
Calf liver : Whole tissue	144	274	0·53
Nucleus	171	322	0·53
Calf kidney : Whole tissue	433	372	1·16
Nucleus	431	410	1·05
Isolated in sucrose solution :			
Calf thymus : Nucleus	86	245	0·35

It is unlikely that sodium and potassium are uniformly distributed throughout the nucleus and cytoplasm. Whole tissue includes a considerable amount of extracellular fluid containing 140 μequiv. of sodium per ml. and only 5 μequiv. of potassium per ml. If the extracellular fluid of the thymus amounts to 10 per cent by weight, there will be 32 μequiv. of sodium and 119 μequiv. of potassium per gm. of cellular mass. Since the cell nuclei occupy 61 per cent of the thymus tissue[8], the content of sodium in the cytoplasm is estimated as 15 μequiv. per gm. and the content of potassium in the cytoplasm as 139 μequiv. per gm. Thus sodium appears to be present in significantly greater amounts in the nucleus than in the cytoplasm at large. The sodium content of the nuclei may have been over-estimated owing to inclusion of connective tissue fragments in the sedimented nuclear fraction. Studies of sodium binding by constituents of this fraction are in progress.

That the sodium and potassium content of the nucleus, or at least of its surrounding cytoplasm, has general functional significance is attested by the finding of Allfrey, Mirsky and Osawa that protein synthesis in isolated nuclei is strikingly dependent upon the presence of sodium ions in the suspending medium[9].

Ultrastructural Organization of Bone

The high mechanical stability of bone tissue is obtained through the combination of the inorganic component hydroxyapatite with the inelastic fibrous protein collagen. Besides serving as supporting tissue, bone also plays an important part in the ionic homeostasis of the organism. A study of the ultrastructural organization of bone should contribute to a better understanding at the molecular level of these characteristic properties of the osseous tissues.

Through combined electron microscope and X-ray diffraction studies at high and low angles[1-4], the following general picture of the submicroscopic organization of bone can be derived. The fibrous matrix of bone, that is, collagen, appears capable of orienting the hydroxyapatite crystallites in a highly ordered way. Thus the rod- or needle-shaped apatite particles are attached precisely along the collagen periodicity. The X-ray evidence[2,3] derived from the profiles of the wide-angle lines and the low-angle particle scatter, and indicating the presence of rod-shaped apatite particles 40–75 A. wide and about 200 A. long, conforms with the results of electron microscope in-

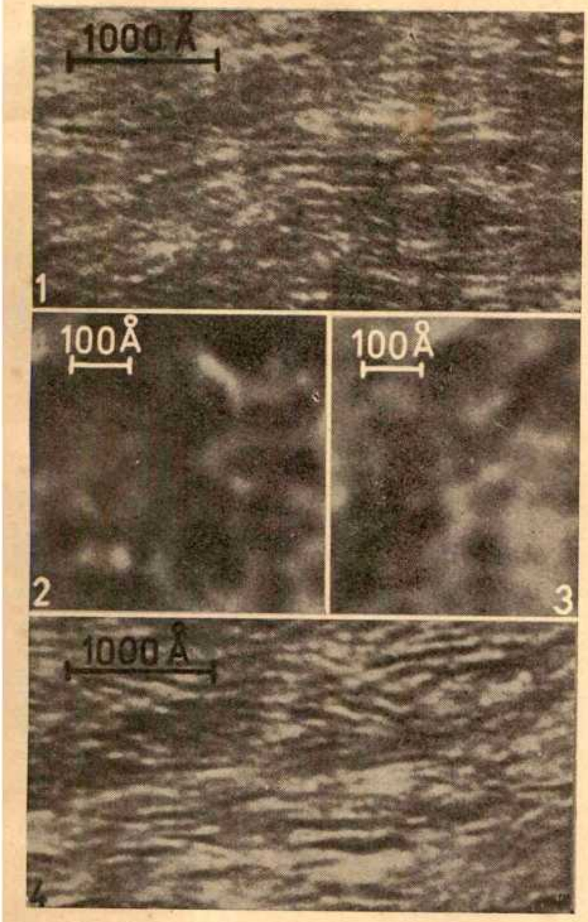

Fig. 1. Ultra-thin section of undecalcified hen bone showing orderly alignment of the apatite particles on collagen. × 200,000
Figs. 2 and 3. Cross-sections of individual apatite particles with surrounding areas of lower electron density. Taken on Kodak High Resolution Plates *KP* 41394. × 750,000
Fig. 4. Longitudinally oriented apatite particles with fine structure. × 200,000

vestigations of ultra-thin sections of bone[1]. The sections of undecalcified bone were produced with a Moran ultra-microtome equipped with a diamond knife[5], and examined at 50 and 100 kV. in an RCA *EMU 3B* electron microscope with compensated objective lens consistently giving a resolution of about 15 A. The examination of a great number of bone sections (human, rat, hen and fish specimens) 50–200 A. thick disclosed the predominance of rod- or needle-shaped apatite particles 30–40 A. wide and about 200 A. long (Figs. 1–4). In cross-sections, the apatite particles are hexagonal or circular and regularly arranged in a network (Figs. 2 and 3). The particles are surrounded by areas of lower electron density, which probably correspond to the dehydrated organic matrix.

Plate-like structures have been described in electron micrographs of bone[6]. In the present study, thin flakes about 500 A. in diameter were seen in some areas. At higher resolutions, however, these flakes seem to be aggregates of thin rods or particles of the same size as those seen in association with the collagen fibres.

Thus both X-ray diffraction studies and electron microscopy point to the existence of rod- or needle-shaped apatite particles about 40 A. in diameter and 200 A. long precisely aligned mainly along the periodic structure of collagen fibres. Further details will be described elsewhere.

Nitrogen Output and Ecdysis in Crustacea

It has been observed[1] that nitrogen output in the shore crab, *Carcinides* is very low prior to moulting, but begins to increase over the last few days. An indication that it rises sharply after ecdysis has now been confirmed in *Asellus aquaticus* (Fig. 1). Feeding individuals were isolated in 2 ml. of water at 23 ± 0·5° C.; the water was renewed daily, and its content of ammonia and amino-nitrogen (as in *Carcinides* the predominant nitrogen-compounds excreted) was estimated by a micro-adaptation of the Sørensen method. Estimates were monitored by the use of Russell's phenate–hypochlorite method[2].

As in *Carcinides*, ammonia output is relatively low 5–6 days before ecdysis and shows a similar incipient rise up to the time of moulting (Fig. 1). After ecdysis it rises sharply and considerably and then declines more gradually to approach the initial minimal value in 10–15 days, that is, about 5–6 days before the next moult in this animal. The decline shows a minor oscillation reminiscent of those superimposed on the general decline in nitrogen output (following an initial peak) after amputation of limbs[3].

The exoskeleton is cast in two portions, often in succeeding 24-hr. periods. In Fig. 1 the mean record for such individuals (*E*) has been separated from that for animals (*A*), which cast both halves in the same

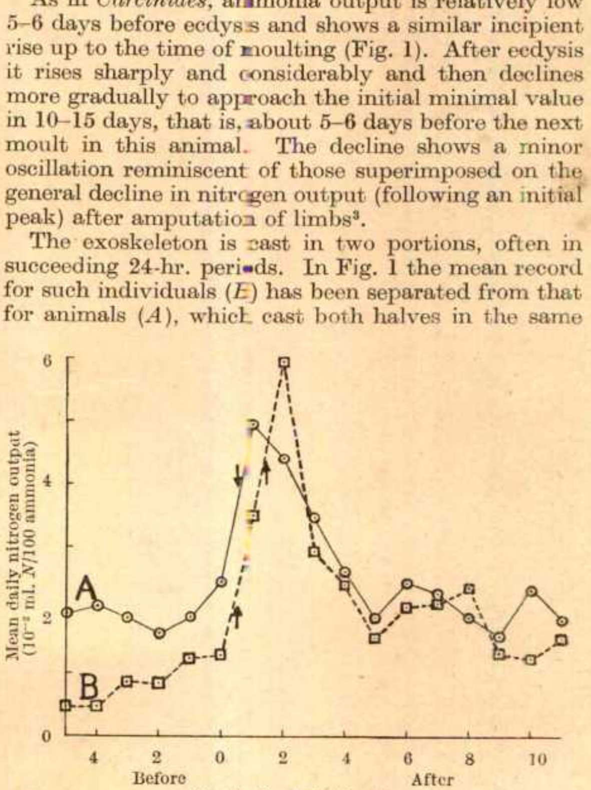

Fig. 1

24-hr. period (arrows mark times of casting). In both groups mean nitrogen output was maximal during the 24 hr. in which the second half was cast; it was not equal in the two 24-hr. periods occupied by ecdysis in *B*. Moreover, in some individuals of *A* output was maximal during the second day after the onset of ecdysis, so that it is not due merely to products of the exuvia, moulting fluid, etc., but is a component of metabolism, culminating soon after the completion of ecdysis. The following minor oscillation in output continued to show the difference in periodicity, of about one day, between the two groups.

The more protracted ecdysis in *B* may be related to the generally low nitrogen output of that group. The eye-stalk hormones of decapods suppress moulting except in the later stages of the intermoult[4], and they prevent excessive nitrogen loss from the tissues[5], and from the body[3]. The low nitrogen output in *B*, therefore, may indicate relatively high activity of a moult-inhibiting hormone.

The period of low nitrogen output in the middle of the intermoult corresponds to that, also hormonally controlled, of maximal cell-proliferation in the cockroach[6], and other arthropods. As in regeneration[7], nitrogen excretion is low when cell-proliferation is most rapid. Amputation of limbs before this critical time can 'put back the clock' of the moult-cycle to synchronize with that of the regeneration-cycle[6]; there appears to be considerable similarity in metabolism between the two cycles.

Relative Growth of Organs and Tissues in Mammals

In the study of relative growth of organs and tissues, there are certain advantages in referring the relative weights to age, throughout the life-cycle. When results are expressed according to the allometric formula[1–3], $y = bx^{\alpha}$ (x = weight of animal, y = weight of organ, b and α = constants), time as an independent variable tends to be eliminated. When, however, the relative weights are expressed in relation to age or its logarithm, they are found to show maximal values at definite periods of the life-cycle, specific for and characteristic of each organ[4]. The curves of the relative weights, as functions of the logarithm of age, tend to follow one of the types in Fig. 1. Thus, in the rabbit, that of the brain follows, from the nineteenth day of embryonic life until adult age, curve 1 of Fig. 1, that of the liver and of the lungs, curve 2, with maximal values respectively at the twenty-fourth and at the twenty-seventh day of embryonic life; that of the kidneys, curve 3, with a maximum between the second and fourth weeks after birth; that of the stomach, curve 4, with a maximum between the fifth and tenth weeks; that of the muscles, curve 5, with a maximum after puberty; and that of the perirenal adipose tissue seems to follow curve 6 with maximal values only late in the adult age. The same sequence of organs, ranged according to periods of maximal relative weights, is likely to be found in other mammals, as is seen from observations of C. M. Jackson[5] on human brain, liver, lungs and kidneys the relative weights of which are maximal in the second, at the end of the third, in the fourth and between the seventh and eighth months respectively.

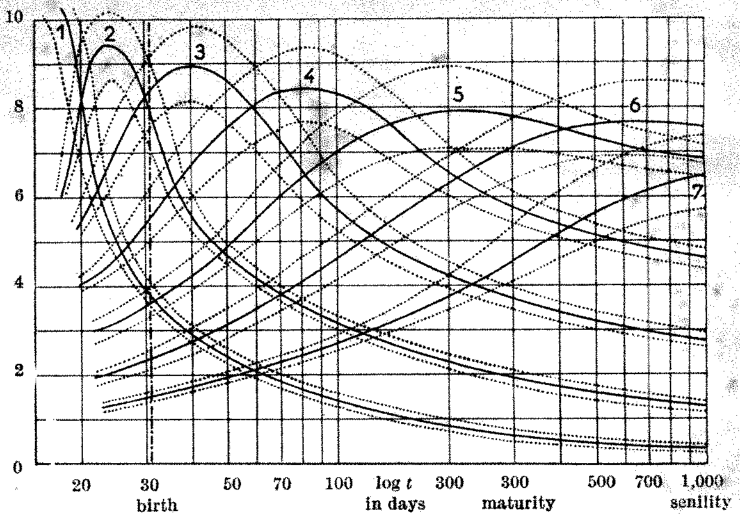

Fig. 1. Types of relative growth of organs, as functions of logarithm of age; ordinate: relative weights of different organs, expressed in convenient units (dotted lines enclose range of variations)

Yet, the growth curves of *absolute* weights of these organs are sigmoid, asymmetric and quite superposable with the growth-curve of the whole body. The existence of maximal values for relative weights seems to be due to the differences in growth-rates of the tissues: organs the absolute weights of which approach most rapidly the limiting weight of adult age have maximal relative weights in early embryonic stages, in opposition to the tissues the absolute weights of which approach slowly the limiting weight and the relative weight of which is maximal late in adult age[6]. When employing the allometric formula, which does not take account of age, positive allometry[7,8] may be observed for increasing relative weights, isometry for their maximal values and negative allometry for their decreasing values[6].

Differences in growth-rates of these organs can be related to the evolution of their chemical composition. Thus the amount of lipoid phosphorus for 100 gm. of fresh tissue, which increases regularly and continuously during embryonic and post-embryonic life until adult age, attains values of 250–270 mgm. per cent in the brain, 150–170 mgm. per cent in the liver, 120–130 mgm. per cent in the lungs, 100–110 mgm. per cent in the kidneys, 60–70 mgm. per cent in the stomach, 29–32 mgm. per cent in muscle and 5–7 mgm. per cent in the perirenal adipose tissue[9]. The same sequence is observed with the amounts of free cholesterol for 100 gm. of these organs[9], with the amounts of proteins and some other constituents.

Thus the sequence of organs is the same, when considering differences of their growth-rates, or differences of accumulation-rates of their lipoid phosphorus, of free cholesterol and of other constituents.

Passive Transfer of a Tumour-resistant Agent by Serum Injections

THE question of passive transfer of tumour resistance (or immunity) appears still open[1-3].

We are working with Walker 256 rat carcinoma, subcutaneously transplanted to commercially available susceptible Wistar albino rats. Among hybrid rats (black or hooded) bred in our laboratory there are individuals capable of acquiring a high-grade resistance (immunity) to this tumour, that is, take at the first implantation and regression after some growth, then failure of growth at further implantations. In a previous experiment[4], we found that rats resistant to Walker carcinoma manifest also a significant delay in growth of 3,4-benzpyrene-induced sarcomas, as compared with the Wistar rats. We are breeding a black strain derived from these hybrids by brother–sister mating; every one of the eight sibs in the eighth inbred generation was found resistant to Walker 256 tumour.

In two experiments we injected pooled serum taken from resistant donors of hybrid origin after regression followed by repeated unsuccessful implantation in them of the tumour used, to Wistar rats implanted with the same tumour.

In the first experiment, summarized in Table 1, 21 Wistar females were implanted simultaneously with the Walker carcinoma and given from the same day either 1 ml. intraperitoneal daily of immune serum from resistant donors, or an equal dose of normal Wistar serum, or left untreated. After 12 days from the implantation the tumours were removed and weighed.

In the second experiment (Table 2) 40 Wistar males were used; one more control was inserted, namely, rats injected with normal pooled serum of donors from the tenth inbred generation of resistant rats not immunized by prior implantation of the tumour. The growth of the tumours was measured by calipers on two diameters and is represented in mm.[2] at the twenty-fourth day after implantation.

Table 1

Treatment	No. of rats	No. of takes	Mean weight of tumours (gm.)	Range of weights
Immune resistant serum	7	7	3 4	0·40–11·50
Normal Wistar serum	7	6	8 6	0·40–17·60
Untreated	7	6	9·3	5 50–14·20

Table 2

Treatment	No. of rats	No of takes	No. of regressions	Mean area of tumours (mm ^{2})	Range of tumour area
Immune resistant serum	10	[illegible]	2	360	25–945
Normal resistant serum	10	[illegible]	–	1,725	25–5,095
Normal Wistar serum	10	[illegible]	2	1,310	150–3,895
Untreated	10	[illegible]	–	1,220	75–3,005

Both experiments are in full agreement in tumour-growth retardation after injections of immunized serum of resistant rats. There are some differences in the number of takes and some regressions in the respective groups, owing probably to the sex difference of both groups (the tumour is a mammary adenocarcinoma which arose in a female; some hormonal antitumour factors may co-operate).

The quantitative evaluation of the supposed antitumour agent passively transferred by serum injections, as well as several other implications, are subject to further experiments (for example, in controls injected with non-immune sera there is a suggestion of either inhibitive or stimulative non-specific influence).

The reason for this successful transfer of a tumour-immunity agent by serum injections—in contrast with other reports—is seen in the contraposition of two homologous but heterogenetic strains, one of which is capable of developing an exceptionally high degree of specific antibody formation. The non-specific, anti-Wistar immunization (a Wistar tumour was implanted to non-Wistar strain of rats) seems negligible, as the total body-weight curves of all groups in the second experiment are nearly parallel.

Fluorescent, Benthic, Pacific Coast Coelenterates

ORANGE fluorescing pigments have been studied extensively in red algae[1,2], where the fluorescence becomes apparent in the moribund plant; but such pigments would appear to be rare in the animal kingdom (see Klüver[3] for evidence of a red-fluorescing pigment in mammals). At depths greater than 10 m. where sunlight becomes deficient in the longer orange and red wave-lengths, divers have sometimes observed brilliantly luminous orange and red animals. Marden[4] noted the phenomenon while photographing a large unidentified anemone in the Red Sea at 20 m., and suggested the animal might have a fluorescent pigment. Our investigations show that certain animals do indeed possess the ability to fluoresce.

During many hours of diving in Californian and Mexican waters, we have found three fluorescent forms, all coelenterates belonging to the sub-class Zoantharia: *Corynactis californicus*, order Actinaria; *Balanophyllia elegans*, order Madreporaria; *Cerianthus* sp., order Ceriantharia. The anemone observed by Marden in the Red Sea was an actinarian. *Corynactis* is an aggregating form, while the others are solitary. Only occasional specimens of *Cerianthus* and *Balanophyllia* fluoresce; but entire small colonies of *Corynactis* (presumably derived asexually from the same individual) may possess the ability, although nearby colonies may fail in this respect. The situation seems reminiscent of pigmentation in the anemone *Metridium*, studied by Fox and Pantin[5], where colour can vary widely from specimen to specimen, yet exhibit constancy in a given individual and is presumably under genetic control. Environment might influence fluorescence, however, if a dietary pigment precursor is needed. It is not known if the intensity of fluorescence under natural conditions changes during the life of an individual; but the amount of fluorescent coloration in specimens of *Balanophyllia* and *Corynactis* kept for two months in our aquarium has not changed appreciably.

Whole specimens of *Balanophyllia* and *Corynactis*, as well as comminuted tissues, were subjected to various physical and chemical tests. Most of the specimens used exhibited a striking orange or red coloration at the time of collection from depths of 20 m. or more. Fresh tissues examined microscopically (× 500) gave no sign of symbiotic algae. Animals exhibited no luminescence when observed in a dark-room. When exposed, however, to well-filtered ultra-violet, violet, blue or green light, the luminous colour observed at the time of collection reappeared. Orange and red light did not excite the fluorescence. The two species, as well as individuals of the same species, differed somewhat in the colours of emitted light; but this could perhaps be caused by variations in concentration of other non-fluorescent body pigments, as well as by differences in the fluorescent pigments themselves. The intensity of emitted light varied directly with the intensity of the exciting light. Specimens that did not exhibit colour on the ocean floor did not fluoresce in the laboratory.

Whole or comminuted animals did not yield any orange fluorescent pigment to either acetone or ethanol. Intact specimens of *Corynactis* kept under acetone for two months have retained their fluorescence apparently undiminished, although they yielded considerable amounts of an orange-coloured pigment, probably carotenoid in nature. Boiling water irreversibly quenches the fluorescence in whole animals after one or two minutes, leaving a dull orangish specimen in the test tubes. The pigment, therefore, is apparently heat-labile, but is distinguished from the algal fluorescent pigment, phycoerythrin, by the stability of the fluorescence to acetone.

Further work is in progress in an attempt to isolate and characterize the fluorescent pigments, to determine their emission spectra, and to study their distribution in the animal kingdom.

This work was carried out during the tenure by one of us (W. J. N.) of a post-doctoral fellowship in marine biology. Grateful acknowledgment is made to Prof. Denis L. Fox, Prof. Carl L. Hubbs, Dr. Francis T. Haxo, and to Messrs. J. Stewart, H. Scotten and R. Ghelardi for advice and assistance. We are indebted to the Division of Marine Botany for the loan of equipment to produce monochromatic light.

Effect of Age of Cotton Seedlings on their Susceptibility to *Rhizoctonia* Damping-off

DAMPING-OFF fungi are known to destroy seedling plants during the first four–six weeks after germination. Tint[1], in his studies on *Fusarium* damping-off of conifers, reported a direct correlation between resistance to invasion and increasing age of host. Matus[2] found that cotton plants were invaded by *Corticium vagum* throughout the growing period, although susceptibility appeared to decline as the plant grew older. Linnasalmi[3] also reported that attack by *Rhizoctonia solani* on cabbage, cucumber and tomato was most severe at the pre-emergence phase. Koba[4] stated that cotton seedlings proved very susceptible to damping-off caused by *Fusarium* spp. at the eight- to fifteen-day old stage when stored food is exhausted and photosynthesis is low.

The present experiment was planned to study the effect of age of seedlings of two varieties of Egyptian cotton, namely, Ashmouny and Giza 30, on their susceptibility to attack by *Rhizoctonia solani*, the cause of damping-off of cotton in Egypt.

The experiment was carried out at three temperature-levels, namely, 9°–18°, 15°–28° and 19°–34° C. Cotton seedlings were raised in sterile soil at a moisture-level of 60 per cent water-holding capacity. As soon as they appeared above the soil-level, twenty seedlings of each variety were exposed daily to the fungus over a period of four weeks. Inoculation was carried out by inserting disks from two-day old agar cultures of *Rhizoctonia solani* on the hypocotyls of the seedlings just above soil surface. Controls with disks of agar free from the fungus were kept under the same conditions. Seedlings, in each case, were kept under observation for a period of four weeks from exposure to the fungus and the number of damped-off seedlings recorded. A representative set of results is presented graphically in Fig. 1. Seedlings

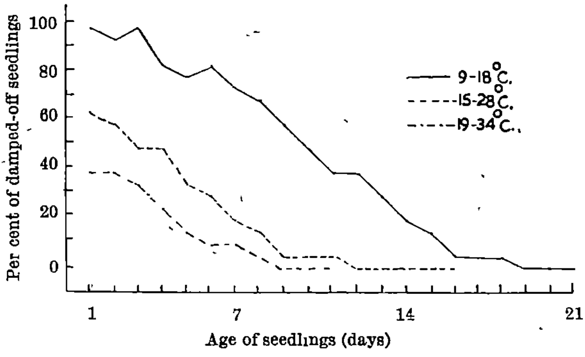

Fig. 1. Effect of age of Ashmouny cotton seedlings on their susceptibility to attack by *Rhizoctonia solani*

inoculated with disks of agar free from the fungus remained healthy throughout the whole experimental period.

The experiments showed that young seedlings of the two cotton varieties are very susceptible to attack by *Rhizoctonia solani*, and susceptibility decreases significantly with increased age of seedlings until they are completely resistant after about 19 days from emergence when raised at 19°–34° C., 12–15 days at 15°–28° C., and 19–22 days when raised at 9°–18° C. The decreased susceptibility with increased age is in full agreement with the previous findings of other investigators; but the fact that cotton seedlings became completely resistant to *Rhizoctonia* attack after a certain period of time, governed by the range of temperature prevailing during germination and emergence, is contradictory to the results of Matus[2], who claims that cotton plants are invaded by *Corticium vagum* throughout the growing period.

Seedlings of Giza 30 variety tend to remain susceptible to the fungus for somewhat longer periods than those of the Ashmouny variety, especially when raised at the lower temperature.

A Chromosome Number New to *Linum*

THE genus *Linum* comprises some ninety species of which, apart from the garden cultivated plants (*L. grandiflorum*), *L. usitatissimum* is of economic importance. Chromosome numbers have been reported in the literature[1–3] for thirty of these species, the range of somatic chromosome numbers being 16, 18, 20, 28, 30, 32, 36, about 57 and about 86.

L. mysorense Heyne is a wild species distributed in the mountainous regions of India and Ceylon at altitudes between 3,000 and 6,000 ft. Material of this species collected from the Western Himalayas and the Western Ghats in India was found by us to possess $2n = 60$ chromosomes, a number hitherto not reported for any naturally occurring species of *Linum*. During microsporogenesis, 30 bivalents were invariably noticed. The pollen was fully fertile and seed-setting abundant.

The high chromosome number and the regular bivalent formation observed during meiosis would suggest that *L. mysorense* is a polyploid functioning like a diploid. In view of this, the diminutive form exhibited by the species has perhaps an adaptive significance. The plants are dwarf, being 8–40 cm. tall, and bear small yellow flowers, about 6 mm. in diameter. The pollen grains measure $60{\cdot}16 \pm 0{\cdot}56\mu$ in diameter and are significantly smaller than those of *L. usitatissimum* ($67{\cdot}50 \pm 0{\cdot}40\mu$), having $2n = 30$ chromosomes. The seeds also are very small—0·8 mm. long and 0·5 mm. broad, the range of corresponding measurements in respect of *L. usitatissimum* being 2·0–4·0 mm. and 1·2–1·8 mm. In peels of the lower and the upper epidermis of fully developed leaves, the stomatal length in the case of *L. mysorense* (33·3μ) was significantly greater than that in *L. usitatissimum* (26·6μ; the width of the stomata was about the same 16·6μ) in the two species.

We are grateful to Mr. V. C. Lele, of Simla, and Mr. V. D. Vartak, of Poona, for the seeds of *L. mysorense*.

Chemical and Biological Determination of Copper in Soil

SEVERAL methods, chemical as well as biological, have been suggested for the determination of copper available to plants in soil. Steenbjerg's[1] method has been used here since 1940, and consists in the extraction of copper from soil with dilute hydrochloric acid of such concentration as to result in *p*H 2·00 of the soil suspension after shaking for one hour. This method has in this laboratory during the past three years been compared with bioassays of copper by means of *Aspergillus niger* according to Mulder[2]. Both methods are somewhat laborious and do not yield readily reproducible results, *inter alia*, because the time of sampling and the length of sample storage influence the results of at least the chemical method.

Investigations have been conducted in order to devise a simpler and more reliable method, and disodium-ethylenediaminetetra-acetate has been tried as an extracting agent, as suggested by Cheng and Bray[3]. The theoretical background for the extraction of heavy metals from soil by means of ethylenediaminetetra-acetic acid was recently discussed by Viro[4].

Preliminary tests were made in order to define the conditions of extraction, etc., and a two-hour extraction with a 0·02-*M* ethylenediaminetetra-acetate solution at its natural *p*H (4·5) was adopted; this results in a state of approximate equilibrium, at least in the case of soils containing less than 2 p.p.m. copper according to the method in question. Copper in the soil extract was determined colorimetrically as the diethyldithiocarbamate complex in the presence of an ammonium citrate solution of *p*H 9·0, which eliminates the interference due to other metals and prevents precipitation of iron.

The analytical procedure is as follows: 10 gm. of air-dry soil is shaken for one hour with 100 ml. 0·02 *M* ethylenediaminetetra-acetic acid solution. The suspension is filtered after standing for another hour, and an aliquot of the filtrate, with not more than 50 μgm. copper, is transferred to a 150-ml. separation funnel; 50 ml. is usually convenient. Approximately 10 ml. of 1 *M* ammonium citrate solution is added, and after thorough shaking a further 1 ml. 1 per cent solution of sodium diethyldithiocarbamate and 15 ml. carbon tetrachloride. After repeated thorough shaking for two minutes and standing until complete separation of the aqueous and the carbon tetrachloride phase, the latter is run through a filter into a small measuring flask or directly into the photometric absorption cell. The colour intensity is measured on

Table 1

Copper, p.p.m. by EDTA-extraction	No. of samples	Copper, p.p.m. means			S.D. bio-assay
		HCl extraction	EDTA extraction	Bio-assay	
0–0·5	17	0·17	0·41	0·94	± 0·557
0·6–1·0	88	0·21	0·83	1·15	± 0·405
1·1–1·5	64	0·25	1·29	1·31	± 0·368
1·6–2·0	34	0·29	1·76	1·59	± 0·409
2·1–2·5	23	0·37	2·30	1·61	± 0·460
2·6–3·0	9	0·33	2·82	1·66	± 0·472
> 3·0	54	1·30	6·99	(>2·50)	—*
Means, 238 samples:		0·26	1·29	1·31	

* This group was omitted from the calculation of means, because the biological method only permits the determination of 2·5 p.p.m. copper and less.

a Beckman spectrophotometer (model *DU*) at 440 mμ and with a 10-mm. absorption cell.

A number of soil samples from untreated control plots in field experiments with copper fertilizers conducted in 1955 were analysed in this way. The copper contents varied between 0·2 and 33·5 p.p.m., with an average of 2·3 p.p.m. in 292 samples. Table 1 shows a comparison between the results for the chemical and the biological method.

Extraction with ethylenediaminetetra-acetate in its present form removed on the average the same amount of copper from the soil as did the growth of *A. niger*, and five times as much as the hydrochloric acid extraction. The agreement between the ethylenediaminetetra-acetate extraction and the bioassay is best in the copper range of 1·0–1·5 p.p.m., probably because the visual estimation of the spore colour in the biological method is most reliable at this level. Fifty ethylenediaminetetra-acetate extracts from soils of varying type showed *p*H values between 4·27 and 4·58 (average 4·43), which is about the same *p*H level as found in the nutrient solution after growth of *A. niger* in the bioassay. This, together with the fact that copper ions are in both cases continuously removed from the soil/liquid system, may explain why these two essentially different methods show the same ability to extract copper from the soil.

The work is being continued, and a more detailed account of the method and its applicability to the diagnosis of copper deficiency in soil will be published elsewhere.

Humus Decomposition in East African Soils

THE macro-respirometer described by Swaby and Passey[1] has been considerably modified while still retaining its chief advantages. The modified apparatus (Fig. 1) is relatively cheap, easy to make and sensitively reflects the magnitude of organic matter decomposition over any desired period. The respirometer vessel is an 8-oz. sample bottle in which the soil (usually 50 gm.) is placed. A small container with about 10 ml. of 2 *M* sodium hydroxide absorbs the evolved carbon dioxide. The unit is immersed in a thermostatically controlled bath 24 in. × 12 in. × 15 in. deep which holds fourteen such units. The hydrogen evolved at the cathode is collected in a 100-ml. burette. The electrodes consist of platinum strips, and the anode was easily prepared by inserting the platinum through a small slit in a 2-in. length of polythene tubing (Fig. 2) about 5 mm. in diameter. This was then joined to the end of the glass tubing (of slightly smaller diameter) leading from the respirometer, using Chatterton's compound. The platinum outside the polythene tubing was bound to the side with fine wire, leaving some for the terminal, and also sealed with Chatterton's compound. The electrodes were joined to a 6- or 12-V. accumulator.

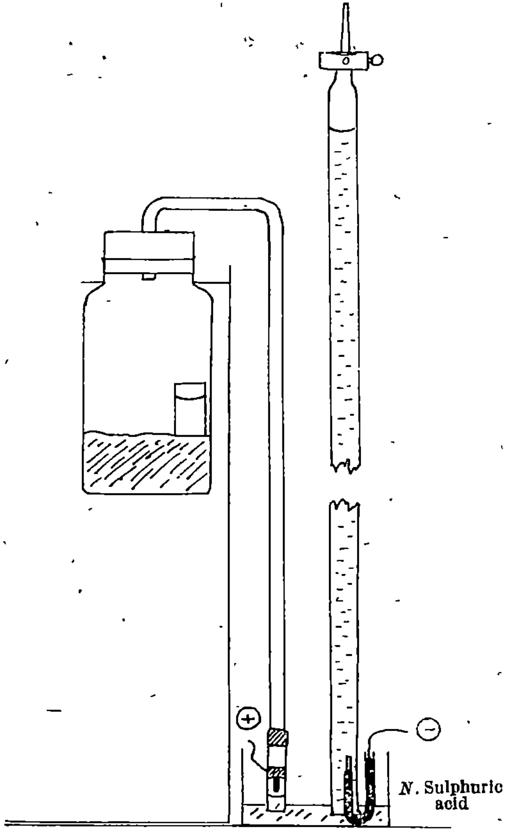

Fig. 1

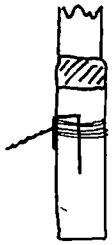

Fig. 2

As oxygen is consumed by the soil micro-organisms carbon dioxide is produced which is absorbed by the sodium hydroxide. This lowers the pressure in the respiration bottle so that sulphuric acid rises in the side-arm, makes contact with the anode and gererates oxygen. This diffuses back into the bottle until atmospheric pressure is restored, after which contact between the sulphuric acid and the anode is broken. This is restored when further oxygen is consumed. The volume of hydrogen simultaneously generated at the cathode is equal to twice the volume of oxygen consumed. Oxygen consumption and carbon dioxide output are usually about equal; but any unbalance is readily shown by respiratory quotient determinations.

With the soil samples so far tested in this apparatus organic matter decomposition followed a first-order reaction, that is, the rate of decomposition decreased with time and was proportional to the amount of decomposable material present. The decrease was shown not to be due to fall in pH, the accumulation of toxic products or the adverse effect of the respirometer environment on microbial activity.

Among the results so far obtained the following are of particular interest. When a soil was air-dried and rewetted an appreciable flush of decomposition resulted. Further successive dryings and rewettings produced effects similar in magnitude, rate of decomposition, and kind of organic material decomposed. The effect lasted for about five days. Oven-drying had a similar effect but of greater magnitude. The drying effect was shown not to be related to microbial stimulation, destruction of toxic compounds, the release of nitrogen, phosphorus and potassium or microbial death with subsequent decomposition of the remains. All the evidence available indicates that the drying effect is one of liberation from the clay of rapidly decomposable material which, under steady moist conditions, is protected by the clay from microbial attack. The magnitude of the effect is related to the degree of drying (influencing both the amount of material liberated and the rate at which it is re-absorbed and reprotected from microbial attack on rewetting); the kind and amount of clay and the amount of organic material associated with it. More exact relationships have yet to be worked out. A single air drying of a forest soil (5·4 per cent carbon) liberated rapidly decomposable organic material equivalent to 0·011 gm. carbon per 100 gm. soil (or 220 lb./acre-6 in. assuming this weighs 2×10^6 lb.). Replacement of this material, assuming it to be of a humic nature, would involve the decomposition of about 1,700 lb. of dry plant material on the basis that this contains 50 per cent carbon and loses 75 per cent of the carbon as carbon dioxide during decomposition to humus.

Similar behaviour was observed with sand–pure clay mixtures to which gelatine was added. Not only did montmorillonite have a much greater protective effect on gelatine decomposition than kaolinite, but also the protected gelatine could afterwards be partly released on successive drying and rewetting, thus paralleling the behaviour of the soil. With kaolinite the drying effect was much less marked. No doubt clays intermediate between these two extreme types would show intermediate effects.

It further appears that the organic material liberated on drying may also be liberated through displacement by other organic compounds. Thus, when gelatine was added to two moist soils, slowly respiring, the respiratory quotient (1·29) for the active decomposition period following the addition was almost identical with that following oven-drying and rewetting and considerably above the theoretical value (0·8) which was obtained during gelatine decomposition in sand–pure clay mixtures. Presumably a rapid exchange took place between the gelatine and the protected organic material, some of the former then being protected and the latter exposed to microbial attack.

These results indicate that part, at least, of the humus fraction under moist conditions is protected from, but not inert to, microbial attack. When it is released either by drying or displacement, it is rapidly decomposed. Further, since decomposition generally parallels ammonia accumulation there should be a quick release, through mineralization, of nitrate and other nutrients. Such behaviour has an obvious bearing on (*a*) the seasonal pattern of humus decomposition, (*b*) the nitrate flush which, as reported by Griffith[2], occurs at the start of the rains and is related to the degree of soil drying, and (*c*) the beneficial effects, so often reported, of burning. It is also possible that the so-called priming action of fresh organic matter on the breakdown of soil humus, generally ascribed to increased microbial activity, is in fact a displacement effect caused by an exchange between the organic matter decomposition products and those already associated with, and protected by, the clay.

There are several references in the literature both to the protective effect of soils and clays against the decomposition of organic compounds, and to the effect of drying on increasing soil fertility. The evidence described above, for the liberation of the protected material on drying, provides a link between these two observations. It also indicates a possible use for the respirometer in soil fertility studies.

Transmission of Beet Mosaic Virus from *Stellaria media* and *Capsella bursa-pastoris* by *Myzus ascalonicus* Doncaster

During the winter of 1955–56, *Myzus ascalonicus* Doncaster was observed hibernating on chickweed (*Stellaria media*) in the field at Gembloux, next to a place where fodder beet had been cultivated in 1955 and harvested in October of the same year. With the view of testing if any of the aphids were bearers of beet viruses, adults and larvæ of the spring generation were put on fodder beet seedlings, var. 'Jaune de Vauriac' for 48 hr. (5–10 aphids a plant), between April 5 and May 2, 1956. After 20–30 days, three of the eighteen tested beets showed chlorotic and yellow translucid circular or irregular little spots on the young leaves. The symptoms were attenuated on the older leaves; these last became narrow and showed interveinal yellowing. The plants were stunted. Later, one of the infected beets showed a regular vein-yellowing on the young leaves.

The sap of one of the infected beets, mixed with 'Carborundum', was inoculated to healthy 'Jaune de Vauriac'; a general mosaic appeared on the young leaves of the five test plants within seven days, suggesting that the virus transmitted was *Beta* virus 2. Using the same source, a transmission was made to beet seedlings by *Myzus persicae* Sulzer

(1–2 min. on the source after 2 hr. fasting, 24 hr. on test plants, 10 aphids a plant). Mosaic was obtained on young leaves within 10–20 days.

The virus was transmitted from infected beet to chickweed seedlings in the same conditions by *Myzus persicae*. It was then re-transmitted from supposed infected *Stellaria* to beet seedlings by *Myzus ascalonicus* Doncaster (1–2 min. on the source, after 2 hr. fasting; ten aphids a plant; 24 hr. on beet). Two of the five tested plants showed mosaic on young leaves after 15–20 days.

According to preliminary results, beet mosaic is also transmissible from infected *Capsella bursa-pastoris* to beet by *Myzus ascalonicus*.

Using beet as a source, *Myzus ascalonicus* was not considered previously as a vector of beet mosaic virus[1]. The results of our trials show that this aphid is able to transmit the virus from infected *Stellaria media* growing in the field, and from artificially infected *Stellaria* and *Capsella bursa-pastoris*. So far as we know, these two weeds seem to be new hosts of the virus.

Myzus ascalonicus is known from the literature as a vector of beet yellows (*Beta* virus 4 Roland and Quanjer), and *Stellaria media* as a host of this virus. Although the transmission of beet yellows from chickweed in the field by *Myzus ascalonicus* has not yet been found with certainty in our trials, the first results indicate that it is most probable.

I should like to thank Dr. Roland, director of the Phytovirology Laboratory, for advice and criticism during this work.

This work was subsidized by the Institute for Scientific Research in Industry and Agriculture.

Effect of Herbicide 2,4-D on Bean Chocolate-Spot Disease

THE herbicide 2,4-D (2,4 dichlorophenoxyacetic acid) has been recorded to affect fungal-host relationship. Ibrahim[1] demonstrated a reduction in the number of rust uredosori to one-fifth on treated oat plants compared with controls. Similarly, Crowdy and Wain[2] recorded a suppression in bean chocolate-spot disease treated with 2,4,6 trichlorophenoxyacetic acid. On the other hand, wheat plants treated with 2,4-D were found to be weakened, stunted and predisposed to a heavier infection with *Helminthosporium sativum*[3]. 2,4-D has been recorded to cause a depletion in the carbohydrate content of treated plants[4,5]; Weller and co-workers[6] observed a depletion of non-reducing sugars.

The present work aims at an evaluation of the possible role of 2,4-D in influencing the relationship between bean plants (*Vicia faba* L., Breed No. 34) and *Botrytis fabae* and the interpretation of such an effect in terms of: (*a*) pathological anatomy of infected treated and untreated plants; (*b*) fungal enzymic activity as influenced by host metabolism in absence or presence of 2,4-D; (*c*) host biochemical changes, in response to 2,4-D treatment, and their possible bearing on fungal development.

Table 1. PERCENTAGE LEAF-AREA INFECTION AND CARBOHYDRATE ANALYSIS (GM. PER 100 GM. DRY WEIGHT) OF LEAFLETS FROM DIFFERENTLY TREATED BEAN CUT SHOOTS

Criteria		Leaflet treatment		
		Fresh	Dipped in Water	Dipped in 2,4-D
Per cent infection		39%	36%	15%
Carbohydrate analysis	Hexose	2·995	2·306	1·957
	Sucrose	4·462	1·619	0
	Total sugars	7·457	3·925	1·957
	Poly-saccharides	3·727	3·932	2·170
	Total carbohydrates	11·184	7·857	4·127

Leaflets of bean cut shoots, previously dipped for five days in pure water or in aqueous solution of 5 p.p.m. 2,4-D sodium salt, or freshly cut, were sprayed evenly with a spore suspension of *Botrytis fabae* to ensure a film of suspension on both leaflet surfaces; similarly, treated cut shoots were left uninoculated to serve as controls. For each treatment, three plants were used; they were kept constantly under humid conditions. The disease criteria were measured on leaves (Nos. 4, 5, 6 and 7), 48 hr. after spraying, by a method adopted by Crowdy and Wain[2]. The number of lesions, on both surfaces of the leaflet, was calculated and the mean diameter of a large number of lesions was determined. Since the lesions are more or less circular in outline, the mean area of the infected lesions could be calculated from the formula (πr^2). The total infected area was afterwards obtained by multiplying the mean area of the lesions on both surfaces of each experimental leaflet; percentage infection could be thus represented as percentage ratio between total infected area and total area of both leaflet surfaces; the latter was determined by planimeter. The results (Table 1) indicated a considerable reduction in percentage infection in cut shoots previously treated with 2,4-D in comparison with those dipped in water or previously freshly cut. In addition, carbohydrate analysis was made by Maskell's method modified by Gawadi[7].

No pathological differences could be detected in the anatomy of infected leaflets under varying treatments. The fungal enzymic activity, as influenced by the 2,4-D treatment of bean leaflets, was tested by Brown's disk method, as follows: juices were squeezed from differently treated cut shoots, cold sterilized by Menon's technique[8], inoculated heavily with *Botrytis* spores and incubated for three days at 25° C. The reaction times for *Botrytis* macerating enzymes, obtained from differently treated juices, were found to be close (that is, ranging between 18 and 20 hr.), denoting a feeble enzymic activity. On the other hand, the herbicidal treatment results in a depletion in the carbohydrate content of the leaf, especially sucrose, which completely disappears; such depletion may interfere with the normal development and pathogenic potentiality of *Botrytis*.

FORTHCOMING EVENTS

Sunday, September 2—Wednesday, September 5

British Association for the Advancement of Science (at Sheffield).—Continuation of Annual Meeting.

Sunday, September 2

At 11 a.m.—(in Sheffield Cathedral)—Religious Service. Preacher the Rt. Rev. the Lord Bishop of Sheffield.

Monday, September 3

At 10 a.m.—Dr. T. Robertson: "The Presentation of Geological Information in Maps" (Presidential Address, Section C).

At 10 a.m.—Prof. D. Whitteridge, F.R.S.: "The Machinery of Posture" (Presidential Address, Section I).

At 8 p.m.—Prof. Sydney Chapman, F.R.S.: "The International Geophysical Year".

Tuesday, September 4

At 7.30 p.m.—Sir John Cockcroft, F.R.S.: "The Future Development of Atomic Energy".

Thursday, September 6—Wednesday, September 12

British Mycological Society (at Sheffield)—Autumn Foray.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Boots Research Fellow (medical or science graduate, preferably with some experience in tissue culture and virology) in Microbiology—The Secretary, The Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Paddington, London, W.2 (September 8).

Draughtsman (man or woman) in the Geography Department—The Registrar, University College, Singleton Park, Swansea (September 8).

Lecturer in the Department of Mechanical Engineering—The Registrar, The University, Liverpool (September 8).

Research Assistant (with a good honours degree in biochemistry or chemistry) for work on problems of dermatophyte metabolism—The Registrar, The University, Leeds (September 8).

Assistant in the Department of Agriculture (Crop Husbandry)—The Registrar, University College of Wales, Aberystwyth (September 10).

Superintendent (medically qualified, experience of medical research including toxicological techniques, and preferably with a first- or second-class honours degree in physiology or other natural science) of the Medical Division, Chemical Defence Experimental Establishment, Porton, Wilts, to be responsible for groups carrying out pure and applied research in physiology, pharmacology, toxicology, biophysics and biochemistry—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting No. S.4618/56/7 (September 11).

Lecturer or Assistant Lecturer (with qualifications in the realm of mathematical analysis) in Pure Mathematics—The Registrar, The University, Hull (September 15).

Chair of Education in the University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, September 20).

Scientific Officers (with a university degree of high standard and evidence of research achievement) in the Defence Standards Laboratories, Department of Supply, Maribyrnong, Victoria, Australia, for research work on paints and protective coatings including: (*a*) physics of the bond between coating and base; (*b*) the chemistry of pigments, fillers and binding media and rheology of paints, etc.; (*c*) actinic and chemical degeneration, embrittlement, etc.; and (*d*) attack from corrosive media and underwater organisms—The Senior Representative (A.P. 63), Department of Supply, Commonwealth of Australia, Australia House, Strand, London, W.C.2 (September 21).

Principal Physicist in charge of the Northern Ireland Radiotherapy Centre—The Secretary, Northern Ireland Radiotherapy Centre, Purdysburn, Belfast (September 24).

Botanist (with at least a second-class honours degree with botany as the main subject, and two years' postgraduate research experience in plant breeding) at the Rubber Research Institute of Malaya, Kuala Lumpur, to engage in the Institute's research programme relating to the improvement of planting material of *Hevea brasiliensis*—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (September 29).

Lecturer (preferably with a major interest in heat transfer, and a knowledge of some aspect on nuclear engineering) in Engineering (Mechanical)—The Registrar, The University, Manchester (September 30).

Lecturer in Orthodontics (Clinical) at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 15).

Laboratory Steward in the Department of Chemistry, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 26).

Fellow (chemist with experience in radiochemical techniques) in the Department of Radiochemistry, Research School of Physical Sciences, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 29)

Chief Mechanic and Technician in the Department of Physics, University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

Assistant Lecturer (honours graduate in agricultural botany and a special interest in plant pathology) in Agricultural Botany—The Bursar, Royal Agricultural College, Cirencester.

Assistant Lecturer (Organic Chemistry)—Dr. L. N. Owen, Chemistry Department, Imperial College of Science and Technology, London, S.W.7.

Assistant (preferably male, with G.C.E. (advanced) in science subjects or equivalent qualification) in the Physics Department (Radioactive Isotope Laboratories), to assist in experimental and clinical work, using various physical and chemical techniques—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3.

Biochemical Technician in the Surgical Unit—The Secretary, St. Mary's Hospital Medical School, London, W.2.

Lecturer in Pharmaceutics—The Secretary-Treasurer, Royal Technical College, Glasgow.

Lecturer (science graduate, preferably in microbiology, with experience in dairy technology)—The Principal, National College of Food Technology, Cranwood Street, City Road, London, E.C.1.

Professor of Horticulture—The Dean, Faculty of Agriculture, University of Alberta, Edmonton, Alberta, Canada.

Research Assistant (well-qualified graduate in chemistry) in Radiation Chemistry in the Department of Physical Chemistry, to investigate some aspect of the radiation chemistry of organic compounds—Prof. F. S. Dainton, School of Chemistry, The University, Leeds.

Research Associate in the Department of Physics to join the 500-kilovolt accelerator group—Dr. Paul Lorrain Institut de Physique, Université de Montreal, Montreal, Canada.

Scientific Officer (honours graduate in chemistry or biochemistry) in the Isotope Section engaged mainly in fundamental biological research using the isotopic tracer technique—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 56/11.

MOLECULAR FLOW OF GASES

by

G. N. Patterson

(University of Toronto)

Size: 9¼″ × 6″ 227 *pages* *Illustrated* 60*s. net*

This book is based on a series of lectures to advanced students in engineering and physics at the University of Toronto. No attempt has been made to give a complete treatment of either gas dynamics or the kinetic theory of gases. The essential purpose of the book is to assist the reader in making a transition in outlook from the continuum to the molecular viewpoint.

POLYESTERS

AND THEIR APPLICATIONS

by

Johan Bjorksten, Henry Tovey

HEALTH AND SAFETY IN INDUSTRY

NOT only Parliament but also public opinion in Britain generally was greatly shocked by the statement about the lack of precautions against fire in factories which was made in the House of Commons on May 18 by Mr. Robert Carr, Parliamentary Secretary to the Ministry of Labour and National Service. Mr. Carr's statement, lucid and admirable in itself, was made on a motion for the adjournment arising out of a fire in a Keighley woollen mill in February in which eight persons lost their lives and which was one of four occurring within a single month in Yorkshire woollen mills. Mr. Carr estimated that between 50 per cent and 70 per cent of the factories covered by the Factory Act of 1937 had no fire alarms; many of them were small and single-story buildings with extremely low fire risks, but nevertheless this is an excessive degree of non-compliance which Mr. Carr admitted could not be allowed to continue.

Most of his statement was devoted by Mr. Carr to an outline of the measures by which the Government proposes to secure greater compliance with the regulations. He said that he is against holding frequent public inquiries; but in the case of serious accidents involving loss of life and much damage, they might be very desirable from the point of view of public morale alone. As a first step, however, the Chief Inspector of Factories is writing to all factory occupiers covered by the regulations, reminding them of their obligation to instal fire alarms; and a rapid survey of the forty to fifty thousand premises affected is being made. A leaflet dealing with the installation of fire alarms and the types of fire alarm most suitable to different premises is also being circulated. Secondly, the Ministry is to speed up its examination of premises by instructing inspectors to make greater use of their existing powers, both in respect of notifying local authorities and also, where necessary, carrying out the examination themselves. Inspectors are being instructed to press employers to introduce fire-drill where suitable; and the decision whether or not to introduce regulations would be made in the light of the success attending such voluntary persuasion. The need for further special regulations to deal with abnormal fire risks is also being examined and it is proposed to intensify general advisory work on fire prevention, both by factory inspectors working in closer collaboration with the fire prevention officers and by publishing suitable literature on the subject.

In outlining this programme of positive action, however, Mr. Carr was careful to put the fire risk in its proper context. Injuries and fatalities caused by fire in industry in total are small, amounting to only one-quarter of one per cent of all the factory injuries reported to his Department. In all, about 180,000 people every year are injured sufficiently seriously to be reported to the Ministry, and some twenty million production days are lost every year as a result of factory accidents, or almost six times as many as were lost last year through industrial disputes. As Mr. Carr remarked, we cannot afford to continue the loss and suffering caused by these accidents.

Mr. Carr's statement received high praise when, some two months later, on July 16, the House of Commons debated the administration of the Factories Acts. Following Mr. F. Lee, who had opened the debate, Mr. Carr then emphasized that while the prime responsibility for health and safety in industry rests on industry itself—both employers and employees—the Government has a four-fold role. It must see that the factory law keeps in step with modern needs and developments; it must see that the minimum requirements laid down in the Acts and in the many codes of regulations made under them are observed; it must be able to advise industry as a whole on these matters; and it must undertake, and stimulate others to undertake, investigation, research and development. In this last connexion, Mr. Carr referred to the recent establishment of an Inter-departmental Committee on Industrial Safety Research, comprising representatives of government, research committees and the Ministry of Labour. Moreover, as a result of discussions with the Industrial Health Advisory Committee appointed in 1954, fresh investigations are proceeding, he said, under the auspices of the Medical Research Council and the Ministry of Labour, into health problems in various industries; for example, into dust problems in the foundry and cotton industries, the dangers arising from the use of toxic solvents and the widespread risk of dermatitis.

On the general situation, Mr. Carr said he believes it should be a matter for concern that the downward trend in the number of accidents reported each year under the Factories Acts up to 1952 had ceased, for during the past few years we have had about 160,000 accidents in factories and 25,000 accidents in other work places involving about 700 fatalities every year. There is a relative decline in accidents caused by power-driven machinery, and up to 66 per cent of all accidents in factories, as well as most accidents at other work places, such as building sites, are now caused in the handling of goods, by persons falling, stepping on or striking against objects, by falling objects or in the use of hand tools.

There are three important aspects of the whole question, with all of which the scientist and technologist are closely concerned, on which Mr. Carr also touched, particularly in speaking on July 16. The scientist and technologist obviously have often in the right of their special knowledge or experience an immediate contribution to make to industrial health and safety. That contribution is most apparent in the work of the Fire Research Organization and in that of the Industrial Health Advisory Committee and related bodies; but it will also be conspicuous in the 'good housekeeping' which Mr. Carr rightly said is an important factor in the prevention of accidents in industry.

Success here, however, does depend very largely on the existence of the right climate of opinion and, as Mr. Carr pointed out, employers and trade unions, jointly and severally, have a grave responsibility, both in education and in creating conditions conducive to the appreciation by everyone who works in industry of the need for safety. That, moreover, is no less true of the work of the factory inspectorate itself. Unsatisfactory standards of compliance with regulations under the Factories Acts and the failure of the inspectors to make greater use of the powers entrusted to them are due partly at least to the general climate of opinion. In the shock to public opinion given by loss of life, action is possible which cannot be sustained unless opinion has thus been brought to realize its necessity.

For legislation on safety matters to be effective, there must be the understanding which will ensure co-operation and support, not simply with industry but also on the part of local authorities and others. In the promotion of such understanding the scientist will often have an important part to play, and it is a responsibility which he should keep continually in mind. It may well be that such responsibility should be discharged increasingly through his professional associations, and this is a matter which should receive further careful consideration from such bodies.

The creation of favourable conditions for health and safety in the factory is, however, first and foremost a responsibility of management. Unless management has fully discharged that responsibility—and not merely complied with the legal obligations but established proper relations with the factory inspectors—the employee can contribute little or nothing, and his co-operation, even if it is secured, may be ineffective or frustrated. The position disclosed by Mr. Carr's statement on May 18 is a serious indictment of management. The evidence of neglect is disturbing; but still more alarming is the evidence of ignorance—not merely the ignorance of factory law, to which Mr. J. C. George and Mr. V. Collins referred, but still more the ignorance of scientific and technical matters.

If the first lesson to be learnt from the position disclosed as a result of the Keighley woollen mill fire is the importance of an alert and educated public opinion, within and without the factory, the second lesson is the vital importance of trained management. Even in the small factory, management to-day demands not merely skill in handling men but also an awareness of scientific and technical factors in many contexts which is not to be acquired without training in which science and technology must have some place. Quite as plainly as the advent of automation, considerations of health and safety in industry emphasize the need of education for management. Without some appropriate technical and scientific training, the manager of even a small works or factory cannot appreciate the factors which make for safety and for health, nor can he fully understand the warnings which a factory inspector may give.

To put the prime responsibility for industrial health and safety on management is not to deprecate the part of the factory inspectorate itself. While the inspectorate has emerged well from this debate, misgivings were freely expressed as to the ability of the Ministry to recruit inspectors of the quality required, and especially as to the numerical strength of the inspectorate. In his statement on May 18 Mr. Carr said that the Minister had just received the report of an inquiry by three senior officers into the staffing and organization of the factory inspectorate and some recommendations about the number of staff have been accepted.

Excluding certain senior posts at headquarters, the present authorized strength of the general factory inspectorate in Great Britain is 322; ever since the end of the War, when it stood at 309, it has been difficult to recruit up to the full establishment, though the number of vacancies had been reduced to 14 in 1953 and the service is now virtually at full strength. Mr. Carr pointed out that the only practical way of organizing the work of the general inspectorate is on a geographical basis, and that if we are to depend for general inspection on technical qualifications, we shall need both more inspectors and an ever greater variety of different specialists. The work of the general inspectorate certainly requires a knowledge of technical matters; but it is in itself an executive job, and many arts graduates have made excellent inspectors. Moreover, increase of the technically qualified content of the inspectorate must be considered in the light of the urgent need for technical man-power throughout the whole economy of Britain, and Mr. Carr suggested that it is in staffing its special branches, and particularly the engineering and chemical branch, that the fullest use can be made of the relatively few with technical qualifications.

Mr. Carr said further that the load on the engineering and chemical branch is particularly heavy, and at the moment it is unable to give as much help as is desirable in dealing with inquiries from the districts or in dealing at first hand with all problems calling for specialized knowledge. Moreover, its work will be substantially increased by the decision to expedite production of several new codes and regulations and advisory publications. It is accordingly proposed to increase the strength of this branch from 18 to at least 44, thus permitting one engineering inspector and one chemical inspector to be stationed in each division. There will also be an increase in the general inspectorate, particularly in order to enable the inspectors to pay more attention to building operations and engineering constructional work.

While the increase announced by Mr. Carr did not satisfy those who had urged a considerable expansion in the inspectorate—of the order of 25–30 per cent—it was accompanied by a reasoned explanation of the basis on which, since January 1, 1955, visits of inspection have been planned. The Ministry is satisfied that the more flexible arrangements then introduced were on the right lines. There is more, however in Dr. Barnett Stross's plea for expansion than Mr Carr was disposed to concede. But whatever the increase in the inspectorate, whether in the numbers with technical qualifications, in women, as Mr. G. Nabarro urged, or in those with non-technica qualifications, the effectiveness of its work largely depends on the support it receives not merely from within industry but also from public opinion generally.

It is in this connexion that salary scales can be important, and here again Dr. Barnett Stross's sustained argument deserves the widespread support of the professional bodies of scientists. It is not simply that, as was strongly urged in the debate, without reasonable salary scales the inspectorate will not attract men and women with the qualifications and character that are essential. If those scales are not comparable with those which men and women of such ability can obtain elsewhere, inspectors will not enjoy the standing in the community which will give the necessary weight to their recommendations and advice. This may well be increasingly true in a Welfare State in which attention is concentrated on material things.

There is a further factor to be considered here. The value of the inspectorate is derived largely from the experience it gains in observing and comparing the safety practices of the more progressive firms. A first-class inspector is able to put such experience at the disposal of new firms or of companies who are entering new and unfamiliar fields. For this to be done effectively demands first-class minds and men whose personality as well as knowledge command respect, and who are able to meet managers and directors on equal terms.

Such men—or women—cannot be obtained on the cheap, nor can we ignore the tendency already noted for their status and influence to be proportioned to the salary scales they enjoy. There are, as has already been indicated, many ways in which scientists and technologists can promote health and safety in industry—by co-operating in the task of education, by direct contributions to 'good housekeeping' and safety measures and practices and by their own professional competence as inspectors or managers. They should not neglect to see, however, that their professional associations lose no opportunity of promoting the formulation of safety codes and practices, or of strengthening the esteem and status to which the factory inspectorate in Great Britain is both richly entitled and on which the effective discharge of its responsibilities depends.

PALÆOGEOGRAPHICAL RECONSTRUCTION

Concealed Coalfields

A Palæogeographical Study of the Stratigraphy and Tectonics of Mid-England in Relation to Coal Reserves. By Prof. Leonard J. Wills. Pp. xiii+208. (London and Glasgow: Blackie and Son, Ltd., 1956.) 0s. net.

THE essential core of geological science lies in the establishment of the nature and ordered succession of events which together constitute the history of the Earth's crust. It is therefore a noteworthy occasion when an attempt is made to fulfil this ultimate aim by the application of the total geological evidence available to a restricted number of events even over a limited area such as the Midlands and North of England. This setting of the pieces into the rational puzzle of living stratigraphy is the life-blood of geological investigation, and by this means the Earth becomes an organism with a physiology of its own. Not all the pieces can ever be present in this puzzle; some have been removed by earlier operations, while other evidence is still deeply buried under the surface skin. It is here that diagnosis based upon related facts plays such an important part, and conjecture and reasoned hypothesis are essential tools. A complete recording of contemporaneous events and their succession represented in geographical pictures which will provide palæogeographical reconstructions of episodes in earth history is desirable. The essential pre-requisite is a sound chronology with short time-intervals, the pulse of the organism, such as can only be provided by effective zonal sub-division based on past life in the form of fossils. Even then, the success of reconstruction is dependent upon the nature and detail of the evidence available, and is furthermore subjective to the particular interest of the palæogeographer and to the fact that it is based upon a knowledge and interpretation of contemporary geological and geographical processes.

Despite these restrictions, careful analysis and diagnosis may unfold the distributions of sea or estuary, of lake or swamp, of mountain and valley, of desert and plain, and, in so doing, the vital physiology governing these occurrences may come to light. In such a manner an evaluation of the original distribution of the rocks is obtained and, in particular, the nature of the agents and processes both geographical and geological which have afterwards limited this distribution by separation into basins or blocks. When the rocks involved contain a national asset such as coal, the information is of prime importance.

With due humility, Prof. L. J. Wills has assembled the puzzle covering the succession of rocks which include the Coal Measures, Permian and Trias of formal stratigraphy. It would be difficult to find a more suitable succession of rocks for such a purpose. The chronology is well defined in the Coal Measures, there is wide diversity of palæogeographical change, and the factual evidence is as great as it could be due to mining and field mapping.

The first part of the book reviews the available stratigraphical evidence and contains the author's interpretation of this evidence and his methodology in its use. The introduction of new terms follows from the application of the evidence to palæogeographical studies, and sub-division of the rock succession from Coal Measures to Trias results. This is effected by the recognition of five 'Palstages' separated by six 'Palevents', a sub-division which does not necessarily follow that of established stratigraphical practice.

The 'Palevent' is a short-lived or sudden palæogeographical event of widespread occurrence and indicated by a marine horizon, a coal seam, or even terrestrial conditions involved in sudden changes of geography, and recorded by tectonic or new lithological features. These include the *subcrenatum* Marine Band, Cefn Coed–Aegir M.B., Brithdir–Tillery–Halesowen event (entry Tenuis zone), Second Malvernian movements, uplift of southern England which produced the Bunter Pebble Beds of the Midlands, and finally the transgression of the Rhaetic Sea. Doubtless other equally effective events could have been used, but these would not necessarily amplify the cardinal points of the author's reconstruction.

The 'Palstage' represents a period of time during which conditions were fairly constant, or subject to consistent changes, or cycles of changes controlled by physical conditions. On this basis there is further sub-division into sub-belts which more nearly follow accepted stratigraphical sub-division.

In order to emphasize the economic aspect of the coal reserves and their relationship to the thick masses of rock which often overlie the main workable coals, the author has instituted a major sub-division within the succession comprising the Coal Measures–Permian–Trias successions. This is his Palevent 2, the widespread invasion of the Coal Measure scene by the Cefn Coed–Aegir marine transgression. Thus below this horizon are recognized the Sub-Aegir belt consisting of a Lower Coal Belt and the Main Coal Belt, the hiatus of coal production in the major British Coalfields, and that part of the sequence most likely to be involved in large-scale coal production. Above the Aegir horizon are Coal Measures (Supra-Aegir Belt), often typical, and which do in fact contain some workable coals; but the higher belts—for example, Haleskeele Belt, Desert Rocks Belt and Bunter–Keuper Belt—show great changes of conditions, particularly in the Midland and North of England coalfields. Thus all rocks above the Aegir Marine Band constitute a 'cover' to the Coal Belt. The lower cover is usually conformable to the Coal Belt and Carbo-Permian in age, while the higher New Red Cover is always unconformable. Thus all the major British Coalfields are, or were originally, "covered coalfields", while those with an unconformable New Red Cover are concealed in the normal sense. Such coalfields may be thus both covered and concealed both in entirety or in part.

The second and third parts of the book are concerned with the specific coalfields of the Midlands and Northern England, and the thicknesses and variability of the various palstages involved are given with the Aegir Marine Band used as a datum. This aspect both of cover and concealment is of important practical value in an assessment of the accessibility of the Main Coal Belt below. The entire cover is the sum of two very different sets of variable factors, and the structure of one part is not always coincident with that of the other. While the original thickness of the covers was controlled by contemporaneous movements, the residual thicknesses of both are mainly determined by erosion following uplifts. For example, the loss by erosion following faulting is greater than that following folding. Some idea of the complexity of relationship between the two covers and between these and the Coal Belt is gained from the thirty structural arrangements which are given for the concealed coalfields.

The complex Midland geological structures are proverbial, but summarily the author concludes that the controlling physiology is "the general principle of deep seated block jostling at depth". Herein lies the responsibility for repetition of movements along the same lines at different periods; these movements, operative in one sense or another from time to time, have led to geographical changes with resultant control over geological accumulation. At the same time the sharp folding and lateral but more usually vertical displacement along faults operative even to post-Triassic times were the resultants of these block movements. No book attempting palæogeographical reconstruction would be complete without adequate illustration; the Palstage maps are intriguing, while the structural maps, isopachyte maps, and plates showing the accessibility of the Main Coal Belt and of the highest worked seams, present the factual and hypothetical evidence in a manner which bears scrutiny.

This book with its original presentation makes a fundamental contribution to geological science, and its methodology constitutes an all too rare occasion in geological literature. There are criticisms which may be directed at the terminology and correlation, but these are outweighed by the value of the broader palæogeographical contribution. Similarly, diagnosis may often be a fickle jade, but it has to be made; better a reasoned hypothesis than even an inspired guess. Here is a pattern derived from the accumulated evidence of geological research in all its aspects, whether these be considered as 'pure' or 'applied'; and that pattern not only indicates the value of such scattered research, but also provokes an inspiring challenge to those concerned with the resources and possible future developments of an important national asset.

L. R. Moore

PROGRESS IN SEMICONDUCTORS

Progress in Semiconductors

Vol. 1. Edited by Dr. Alan F. Gibson, Prof. R. E Burgess and Prof. P. Aigrain. Pp. vii+220. (London Heywood and Co., Ltd., 1956.) *50s.* net.

THE discovery of transistor action in 1948 set off many new studies of the physics of semiconductors; the search for satisfactory techniques of making transistors, phosphors and infra-red detectors led to many chemical and metallurgical studies. Application studies were also built up rapidly. So far, accounts of most of the later studies appear only in the original papers, the numbers of which are mounting rapidly and the collective reading of which is becoming an ever-increasingly formidable task. Relief has been afforded occasionally by some review articles, notably those appearing in the reports of two international conferences and in two issues of the *Proceedings of the Institute of Radio Engineers*. Something more regular is needed, however; integrating papers confined to, at most, one branch of the subject would be welcomed by newcomers to that branch and by workers in the other branches and critical reviews would freshen the minds of all.

The publishers and editors of "Progress in Semiconductors", which is to appear annually, recognize the needs and have set out to fill them. This firs volume has seven articles; physics predominates not surprisingly in view of the editors' background and not unfairly in view of the proportion of research it still attracts in the subject. The first article, how ever, is more general; it summarizes the advances in silicon, from preparation and properties to applica tions. It is well balanced and factual, but leaves th reader to deduce the current problems. The nex chapter directs attention to the important par played by germanium filaments in physical studies it describes the preparation of filaments and the methods by which they have been used in measuring drift mobility, diffusion constant, life-time, surfac recombination velocity, injection ratio at a point con tact, and noise. The theory of the Seebeck effect in semiconductors is explained in the next chapter. Thermoelectric effects with metals have for long provided thermometers; with semiconductors they promise other uses. The chapter is timely and should prove a useful reference for some years. Prof. G. F. J. Garlick contributes a chapter on the electrical properties of phosphors. Experiments can be more accurately defined now that single crystals of some phosphors can be grown, but results still need cautious interpretation. The next chapter explains the limitations of conventional junction transistors at radio frequencies and restates the merits of *p-n-i-p* and unipolar transistors. Written before the middle of 1955, it contains no mention of graded bases or of diffusion transistors. French authors provide the last two chapters, on the photo-magneto-electric (PME) effect and on field effects. The former effect has received much attention lately, and its finer points are better understood; it is being used to measure some basic properties of semiconductors and is well described here. Progress with field effects has been slow; the interpretation of results is hindered for lack of independent methods of measuring some surface properties.

The volume cannot escape some criticisms. The information content, per unit area, of some of the diagrams, particularly six at the beginning of the last chapter, is very low. The writing, in places, lacks the clarity and flow that one expects of good review articles—for example, those of "Advances in Electronics and Electron Physics", which admittedly has had several years in which to get into its stride. None the less, the new series has made a good start.

ENZYMOLOGICAL RECIPES

Methods in Enzymology

Edited by Sidney P. Colowick and Nathan O. Kaplan. Vol. 2. Pp. xx+987. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 23.80 dollars.

THIS is the second of four volumes dealing with methods and techniques in enzymology, the first volume of which was published last year (see *Nature*, 177, 810; 1956). It completes the part of the series which is devoted to the preparation and assay of individual enzymes. The remaining two volumes are to cover preparation of substrates and special techniques used in the study of enzymes.

The 152 articles in this volume are arranged in five sections, namely: enzymes of protein metabolism; phosphate metabolism; nucleic acid metabolism; coenzyme and vitamin metabolism; and finally, respiratory enzymes. This arrangement of enzymes according to their functional relationship in the metabolic pattern tends to obscure important similarities between enzymes carrying out similar reactions; for example, the phosphokinases are scattered throughout the book, and indeed throughout Vol. 1 as well.

More than a hundred and thirty authors have contributed to the present volume, and the articles naturally vary considerably in style and quality, although there is a fairly standard system of headings, with sections on assay method, purification procedure, and properties for each enzyme. Some articles give a useful short review on the occurrence and metabolic importance of the enzyme being treated, together with several methods of preparation. In other cases the article is virtually a reprint from the original literature of a single paper on the preparation of the enzyme. The multiplicity of authors has led to a certain amount of duplication; for example, Elliott's method of preparation of glutamine synthetase from peas is quoted verbatim on p. 339 and again (under the heading of γ-glutamyltransferase, with which it is identical) on p. 264. In this case the reproduction of the original paper includes an inconsistency, most annoying to the worker who is attempting to use the procedure, which is probably a misprint in the original (3·7 l. is given as 0·05 vol. with respect to a volume which is more than 144 l.).

Only a part of the material in this book will be of any permanent value. When an enzyme has been obtained in a pure state in high yield, the method may become classical but many of the preparations given are necessarily merely extracts of tissues of exceedingly low purity, which will soon become outdated as research on the enzyme in question proceeds. On the other hand, as a summary of present knowledge of enzyme purification, the two volumes are remarkably complete.

From such a large collection it is difficult to single out any for special mention, and in any event, such a mention may merely reflect the interests of the reviewer. However, as samples may be mentioned some excellent accounts of the proteolytic enzymes of digestion, of the more well-defined components of the blood-clotting system, of the bacterial system which cleaves aromatic rings, and of the enzymes which break down coenzyme I. The whole section on the enzymes of coenzyme metabolism is perhaps particularly useful, as many of these enzymes are of very recent discovery and it would be difficult for the newcomer to the field to track down the relevant papers. A certain amount of material in this section has not been published elsewhere.

There is no question that this is a work which should be in every biochemical library and will be of value to all who at some time or other, for research or teaching, have to prepare enzymes.

Edwin C. Webb

MOTIVES IN THE CLASSROOM

Educational Psychology in the Classroom

By Prof. Henry Clay Lindgren. Pp. xv+521. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1956.) 40s. net.

THE educational psychologist is increasingly turning his attention to classroom problems; but this does not mean that he has all to teach and nothing to learn. The situation in the classroom is, however, more complex than earlier generations of teachers assumed and calls for the kind of understanding that contemporary psychology can supply.

Prof. H. C. Lindgren's book is written in this tradition and in a helpful spirit for the teacher. He stresses the value of group methods, of active learning and of the partnership between teacher and taught. Authoritarian methods are condemned. We understand that unless a pupil likes school, little headway will be made, for in a way the teacher is leader of his class only in so far as he is made so by his pupils. Lindgren also draws on sociological studies such as "Elmtown's Youth" and insists that to know a child's social class is very important to the teacher. He is well aware that, in its extreme form, this type of relationship may be peculiar to the American way of life; but the British reader will find much in these views worth giving a try.

Lindgren stresses also the relativity of human experience. Teachers often judge a pupil's actions in terms of their own values and experiences, failing to realize that a different set of values and perceptions may operate for the pupil. We need to look for less obvious motives; and to try to view things as the pupil sees them is to be commended.

In a book which emphasizes learning in and from the group in a relatively free and incidental way, learning theory is taken mainly from gestalt and field theory. In the last part there is material on assessing the results of learning, tests, guidance, children with special needs and the psychology of teaching. It is copiously illustrated with photographs and cartoons; but the British student may find them a little unusual and perhaps redundant. The text contains relevant non-technical examples, and there are suggestive exercises and full lists of references, particularly on the social and dynamic side.

The writer fuses the two themes of socialized group action and of a free learner enjoying equality of status with parent and teacher. On this matter of equality of status, I feel one must ask whether young children and even adolescents do not often expect adults to know more, to act as if they do, to impart their knowledge, to order the child's world a little and to allow him that amount of freedom he can manage. Freedom can be a burden as well as a boon. For all this, the book is a stimulating antidote for those who assume too readily the authoritarian role and hence are insensitive to the real forces in classroom life. E. A. PEEL

EDUCATION IN THE FREE WORLD

The Citadel of Learning

By James Bryant Conant. Pp. vii+79. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1956.) 16s. net.

THIS book is made up of three essays on the work of scholars and teachers and its relation not merely to the well-being of the United States but equally to the maintenance of freedom throughout the world, and the essays should command the attention and challenge the thought of many who will never be persuaded to read those scholarly volumes which have already appeared under the American Academic Freedom Project of Columbia University. It is no detraction from the excellence of the studies of Profs. R. Hofstadter, W. P. Metzzer and R. M. MacIver to suggest that in less than eighty pages Dr. J. B. Conant has given the gist of the story of the development of academic freedom in the United States and its meaning for the free society to-day. Indeed, although, especially in the second and third essays, he writes essentially in an American context, his wider vision gives his comments even greater relevance to the situation elsewhere than Prof. MacIver's penetrating comments and analysis, and British readers will be as grateful to Dr. Conant as those American readers to whom his volume is primarily addressed. It may be placed with those other notable contributions to Anglo-American understanding for which we are already indebted to a man who, as well as being a scientific worker and university administrator, lately served his country as United States High Commissioner and Ambassador to Western Germany.

The first of the three essays, which gives its title to the book, might be described as reflexions on the functions of a university provoked by a phrase freely translated from some words of Stalin. More particularly, Dr. Conant illumines the international function of a university—the advancement of learning—by examining what has happened among communities of scholars on the other side of the Iron Curtain, emphasizing that, from whatever angle art, literature, philosophy and science are viewed, they have been the outcome of both conflict and co-operation, a struggle among beliefs and a sharing of beliefs. Such creative activities are not confined to a university, but these are the only terms on which those within the university have lived and worked effectively for the advancement of learning in the past, and they are the only terms which will ensure the safety and vitality of the university as a citadel of learning in the future. Freedom and tolerance, Dr. Conant argues, go hand in hand in matters of the spirit; controversy is essential to a healthy condition in such a citadel.

In his second essay, entitled "An Old Tradition in a New World", Dr. Conant summarizes in masterly manner the re-shaping, within a century, of European ideas about schools and universities into a characteristic American tradition expressing the two ideals of equality of opportunity for all youth and equality of respect for all honest citizens. His summary, moreover, is critical, for though Dr. Conant believes these two ideals or doctrines are as significant for the future as for the past, he is not satisfied that American education has in all respects even started to outline the problems which the new position of the United States in the world has forced upon it. Some of these problems are indicated; by and large the same problems confront education in Britain to-day, so that this essay not only contributes to the understanding of American institutions and problems but should also stimulate thought among British readers about their own problems and the adaptation of their own institutions to the needs of the world in which we live.

When, in his last essay, Dr. Conant focuses his attention on some basic problems of American education, he is no less stimulating and provocative of fresh thinking to readers of other nationalities in considering problems of professional and technological education, the place of research in a university and the relations between teaching and research. There is a place for the heretic and the spirit of free inquiry in the education of professional men and women. "If the free world is to preserve that spirit which has made possible the growth of Western culture, the future leaders must as young men be impregnated with this spirit. They should early come to learn the significance of dissent and be exposed to an intellectual atmosphere where vital differences of opinion are not merely tolerated but encouraged." Dr. Conant's shrewd comments and criticisms point to dangers which are encountered in Britain no less than in the United States, and his wise counsel bears as closely on the expansion of British university institutions as it does on the re-shaping of American institutions to meet growing demands. R. BRIGHTMAN

Control of Nuclear Reactors and Power Plants

By M. A. Schultz. (McGraw-Hill Series in Nuclear Engineering.) Pp. viii + 313. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 52*s.* 6*d.*

THE author sets out to analyse the characteristics of nuclear power plants, primarily using servo techniques. As an example of the method, skilfully applied to a set of problems, the work is of value; although perhaps more to those whose interest is in the method rather than the problems. This opinion is advanced for two reasons. First, the servo method gives qualitative information on stability, rather than quantitative data on the course of transients. The latter problems, in my experience, predominate in the field of reactor control. Particularly in the base-load power reactors now being designed in Britain, there is little difficulty with stability against oscillatory tendencies, simply due to the wide spacing of the time-constants of the effects which comprise the control sequence. Certain problems might conceivably arise from distributed effects, but these would not be amenable to servo methods of solution. Second, the design of a control system for a nuclear reactor is a project which justifies considerable, one might say unlimited, attention and effort. If the particular equations cannot be solved by conventional methods, numerical solutions using digital computors, or graphical solutions using analogue computors, could be obtained. The speedy methods of frequency diagrams, admirably adapted to the repetition design of similar systems, seem too cursory in the present context.

The curves of Figs. 3.1 and 3.2 appear to be reproduced on too small a scale to be useful, and, so far as they can be read, do not satisfy the obvious condition $\Sigma A_j = 1$.

On p. 122, eqn. 5.3 should read $v = A\omega \cos \omega t$, and on the same page, the statement "rod mass $= m$, in poundals" should presumably read "in slugs".

Referring to Fig. 10.7, the point of inflexion at 0·1 sec. suggests that a period of artificial acceleration is followed by deceleration, followed by acceleration again under gravity. This does not correspond with the explanation in the text. J. H. BOWEN

High Vacuum Technique

Theory, Practice, Industrial Applications and Properties of Materials. By J. Yarwood. Third edition, revised. Pp. vii + 208. (London: Chapman and Hall, Ltd., 1955.) 25*s.* net.

SINCE the end of the Second World War, when the second edition of J. Yarwood's well-known and useful handbook of vacuum practice was first published, both the demand for, and the supply of, vacuum apparatus have increased manifold. In addition, several innovations have been introduced: ultra-high vacua of 10^{-10} mm. of mercury and less have been attained and measured, and many new applications of vacuum procedures have been made. Nevertheless, fundamentally, vacuum practice remains the same, and in the third edition of his monograph Yarwood resists quite rightly the temptation to omit the standard basic material in favour of more attractive modern applications of vacuum techniques to industrial processes.

The text is illustrated by a large number of line-drawings which are remarkably clear, well drawn and beautifully reproduced. There are an extensive bibliography and numerous references to scientific articles and manufacturers' catalogues. Many useful data are contained in the several tables which are scattered throughout the text. One wonders, however, why the author did not adopt some standard accepted form for the abbreviations of the titles of the periodicals to which reference is made, and in addition why some authors' names are quoted in full and others not. But these are trivial blemishes, and the volume still remains one of the best elementary text-books on the subject of vacuum technique to which to introduce students of science, and for industrial and other research workers to have close at hand for rapid reference.

Methods of Mathematical Physics

By Sir Harold Jeffreys and Bertha Swirles (Lady Jeffreys). Third edition. Pp. x + 714. (Cambridge: At the University Press, 1956.) 84*s.* net.

THIS important work first appeared in 1946 (see *Nature*, **160**, 139; 1947); four years later a second edition, considerably revised, was issued. A third edition is now called for, and the authors have made further improvements, though on a much smaller scale. "Some theorems are stated more explicitly, a few proofs are added, and some are shortened"; others are generalized or given in more detail. After ten years, a book so widely used must now approach complete freedom from errors and misprints, thanks to the aid of many readers. The index combines subject and author references; the latter might appropriately include mention of acknowledgment in the prefaces.

Intuitionism

An Introduction. By Prof. A. Heyting. (Studies in Logic and the Foundations of Mathematics.) Pp. viii + 132. (Amsterdam: North-Holland Publishing Company, 1956.) 13.50 guilders; 27*s.*

TO the intuitionist, mathematical existence is synonymous with construction; to inquire whether a number which cannot be constructed nevertheless exists is to go outside the domain of mathematics, and enter that of metaphysics. The programme is positive, but may also claim the negative virtue of avoiding some of the paradoxes which beset the logical foundations of classical mathematics, so the classical mathematician may well wish to know how much of his domain must be sacrificed to purchase this freedom, and to see, for example, how a theory of measure and integration can be built up in a domain in which a bounded monotonic sequence need not tend to a limit. Under Brouwer's primacy, much work has been done in The Netherlands, and Prof. A. Heyting, of Amsterdam, has had the happy idea of producing a missionary tract. In the first chapter, a dialogue between an intuitionist, a classical mathematician, a formalist and others sets the stage and the intuitionist offers to produce his wares for inspection. Thus chapters on algebra, integration, logic, are specific examples of intuitionistic mathematics at work, cutting a cautious path through the tangle of difficulties, with a good deal of useful comment. Reading the book still requires the utmost concentration, but granted this, the fascination of the topic begins to emerge and it may well be that some young mathematicians will be encouraged by it to meet Prof. Heyting's call for more workers in this field. Those who feel themselves to be too old to learn new tricks will nevertheless be grateful to the author for this successful attempt to explain the intuitionist point of view and programme.

T. A. A. BROADBENT

CENTENARY OF THE UNIVERSITY OF MELBOURNE

By PROF. JOHN S. TURNER
Department of Botany, Melbourne

THE University of Melbourne held its centenary celebrations during the week beginning August 13. Delegates from a hundred universities presented addresses. The oration was given by Sir Ian Clunies Ross, and fifteen honorary degrees were conferred in the new Wilson Hall. There were Vice-Regal and Government receptions, and the Council of the University gave a banquet in the Hall at the conclusion of the ceremony.

To-day the metropolitan area of Melbourne sprawls over some 200 square miles and houses 1½ million people, more than 60 per cent of the population of the State of Victoria. In its University there are about eight thousand staff and students. In 1840 less than half this number of people were living in the raw pioneer township on the banks of the Yarra. Twelve years later gold was found, and the young Colony began its first hectic burst of growth. The opportunities were then even greater than now. Hugh Childers, later to be British Chancellor of the Exchequer under Gladstone, and just down from Cambridge, became Auditor-General in 1852, and a year later he put through an Act to found the University of Melbourne. This was four years before the first election to the new Parliament. In 1854 Mr. Justice Redmond Barry became the first chancellor. The obvious site for the University, the Domain, now the centre of Melbourne's great system of parks, was then covered with the tents of migrants, and 100 acres were allotted to the University two miles out of town in almost virgin bush. Here was built the first wing of a small stone Gothic quadrangle, which served the University as its home for another twenty years.

The University made slow progress in a community of pioneers and gold-miners. During the next fifteen years it granted only a hundred degrees. Nevertheless, it was wisely served by its first administrators and teachers. In 1853 there were only four universities in Britain, and Melbourne, therefore, had an unrivalled opportunity of attracting first-rate men to its chairs. The first four professors who lived and worked in the little stone quadrangle were exceptional men. Two of them were from Ireland: Sir Frederick McCoy, F.R.S., the first professor of natural science and the founder of Melbourne's National Museum, and W. E. Hearn, the great professor of law and history. M. H. Irving (classics) was from Oxford, and W. P. Wilson (mathematics) from Cambridge. They were followed by G. B. Halford in 1863, the holder of the first chair of the new Medical Faculty.

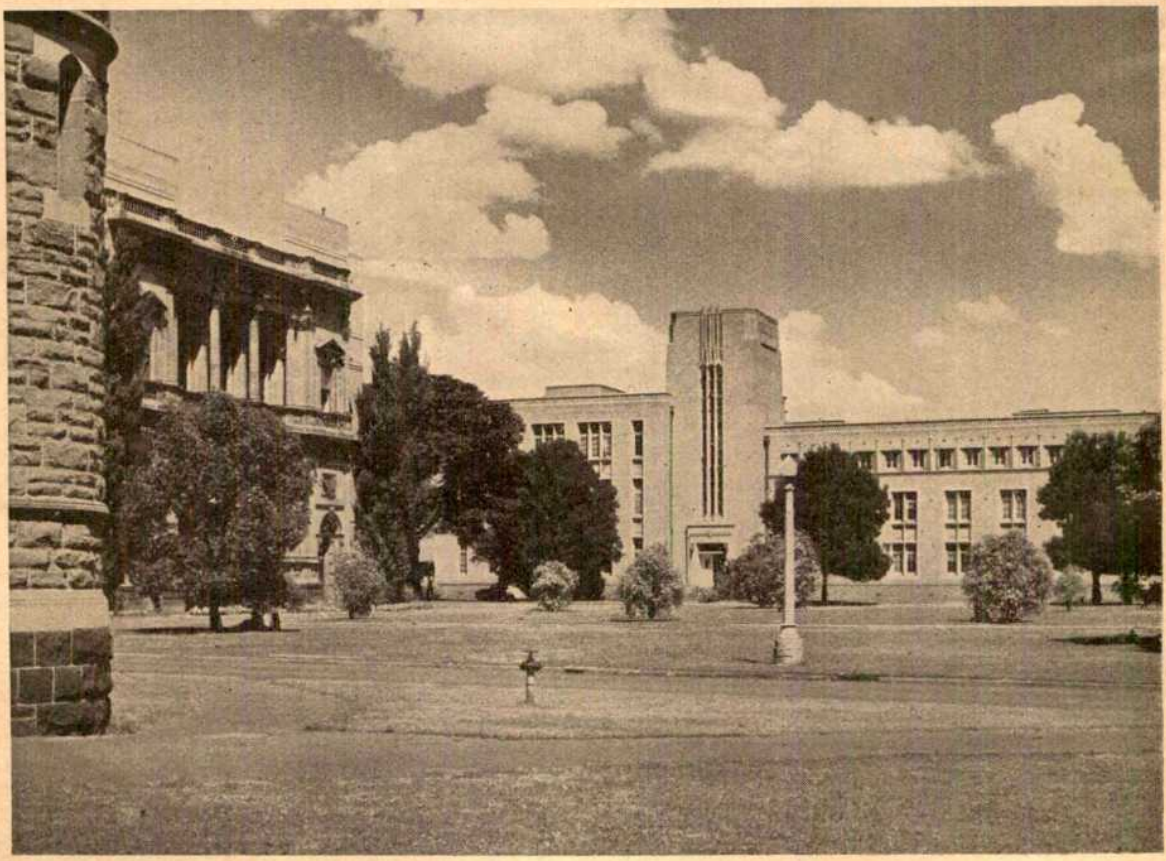

Fig. 1. The University of Melbourne. Left to right: Zoology, Commerce, Chemistry Schools

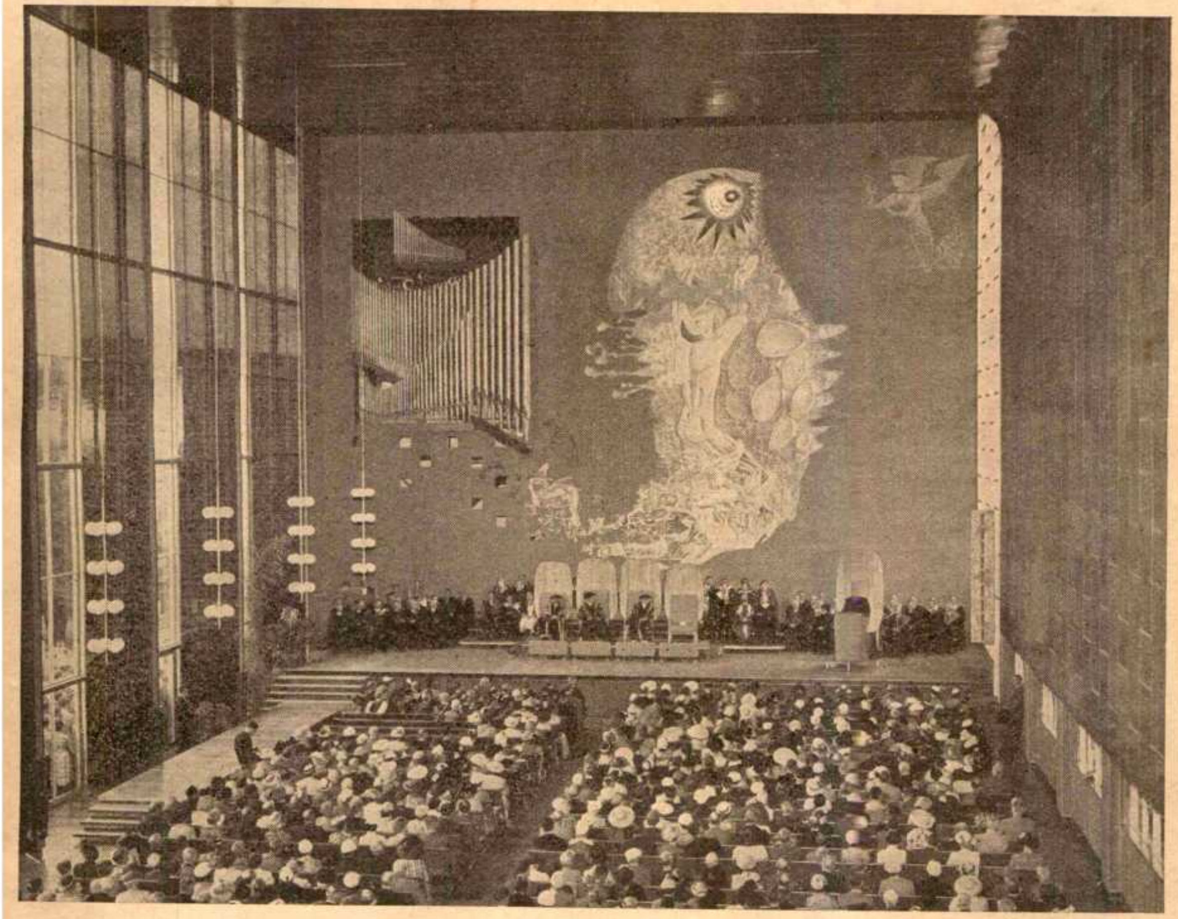

[*Photo : Visual Aids, University of Melbourne*

Fig. 2. Wilson Hall, University of Melbourne. The Premier of Victoria, the Hon. H. E. Bolte, addressing the meeting at the opening of Wilson Hall by the Governor, Sir Dallas Brooks

The University began its first move forward in the eighties. By that time most of the professorial houses were ready in the grounds—great red-brick Victorian mansions, now largely used for housing the overflowing departments. Five new professors, four of them Melbourne men, were appointed in 1882, and they were soon joined by four newcomers from Britain, who set a standard of scholarship and learning which Melbourne has consistently retained. They were T. G. Tucker (whom Cardinal Newman called the first Greek scholar of the day), David Orme Masson, chemist, Baldwin Spencer, the biologist who pioneered anthropological work on the aborigines, and Thomas Lyle, the first of a number of distinguished physicists. All three scientists became members of the Royal Society of London, and were later knighted, and their names are still remembered with affection and gratitude. The putation they built up for the infant University attracted others, and out of a long list it is perhaps fitting to mention Sir William Harrison Moore (law), Sir Ernest Scott (history), E. J. Nanson and J. H. Michel, F.R.S. (mathematics), T. H. Laby, F.R.S. (physics), Sir Charles Martin, F.R.S. (physiology), . W. Gregory, F.R.S., and E. W. Skeats (geology), W. C. and W. N. Kernott and H. Payne (engineering), W. R. Boyce Gibson (philosophy), G. W. L. Marshall-Hall (music), Sir Harry Brookes Allan (pathology), A. J. Ewart, F.R.S. (botany), W. E. Agar, F.R.S. (zoology), R. J. A. Berry and F. Wood-Jones, F.R.S. (anatomy) and L. F. Giblin (economics).

The University has been fortunate also in its administrators—it has had great legal chancellors like Sir Redmond Barry, Sir John Madden and Sir Charles Lowe, and an able succession of registrars. It is governed largely on British and Scottish lines, and although the supreme control is in the hands of a lay Council, a great deal of the government of the University is left to the Professorial Board and the Vice-Chancellor. The University made its greatest step forward into the modern period when it appointed Mr. (now Sir) Raymond Priestley as its first full-time vice-chancellor in 1936. Although he stayed only three years, his drive and energy saw the completion of the fine new Students' Union and the new Chemistry School. An inspiration to the staff, he was also instrumental in bringing town and gown together into a collaboration which resulted, under the present vice-chancellor, in the centenary appeal which raised more than half a million pounds. Priestley was followed by Sir John Medley, from Winchester and New College, Oxford. A man with wide contacts in the educational and business worlds of Australia, he brought to the University something of the grace of another period which is badly needed in an age of technocracy. He had to cope with the extremely difficult post-war period, when student numbers rose to alarming proportions. Under his rule, and that of his successor, Prof. G. W. Paton, an unusually friendly spirit of co-operation arose between the members of the different faculties. The University has remained well balanced in the humanities and science, and has built up exceptionally strong medical and technological faculties over the past seventy years.

As may be expected in a metropolitan university, only a small proportion of the undergraduates live in the five colleges. Four of these are church foundations, and they have played an important part in the University, largely owing to the ability of their heads, of whom the Rev. E. H. Sugden, Sir John McFarland, Dr. Alexander Leeper, Sir John Behan, Dr. D. K. Picken and Father Murphy are the best known.

The University still occupies its original site, and here are gathered twelve faculties, a staff of 427 full-time academics with 812 part-time teachers, and a student body of 7,500. The growth of the University has been largely unplanned, and the architectural styles vary from the original Gothic of the quadrangle to utilitarian red brick, Glaswegian academic, Scottish baronial, Renaissance and the plain Army hut, the fruit of two world wars. Lawns and some trees still survive from McCoy's original ambitious plantings, and there are now signs of considerable improvement. The Union, Chemistry School, Geology wing, the new Arts block and, more recently, the Beaurepaire Physical Education Centre and the magnificent new Wilson Hall (which replaces an early benefactor's Gothic Hall) are a sign of a new dignity to come. With a massive immigration and considerable inflation, the University is only slowly finding it possible to erect new departments; but the long-awaited Library is about to rise, and with it new engineering buildings and the first floors of a new Biochemistry School, the gift of Sir Russell Grimwade.

Since the Second World War the University has taken an increasing interest in the Near East, and there are some three hundred Asian undergraduates reading for degrees at present. A new college, International House, is nearing completion, and this will accommodate equal numbers of Australian and overseas students. Several senior members of staff have travelled recently in Asian countries to advise on educational matters, and a new Department of Indonesian Studies has been set up.

The University has played a great part in the training of leading public and professional men in Australia and elsewhere. This is not the place to assess its achievements in scholarship; but it must be remembered that until recently little attempt was made to encourage indigenous research schools above the M.Sc. level. A characteristic of the young Australian is his urgent desire to see the world, and especially Britain, and this has led to a constant outward stream of graduates, mainly to Oxford, Cambridge and London. While we must be grateful to these universities for the training they have given to these men and women, it must not be forgotten that they, in their turn, have undoubtedly added to the prestige of the research schools in Britain. The Ph.D. degree was instituted in Melbourne in 1946, and now most departments are building senior research groups. This is a matter of some difficulty because of the increasing demand for our students by industry and the Government services. The future of the University is at present in the balance. It is a hundred years old, but active and vital, still growing rapidly and bursting at the seams. In spite of large annual financial grants by State and Commonwealth Governments and some splendid endowments, the University will not be able to cope with the demands which will shortly be made upon it. The State high schools are accepting six thousand new enrolments and the Education Department is building ten new high schools per annum. It must often be difficult to decide on the proper date for the foundation of a new university; but no such problem exists in Melbourne to-day. The State needs another university and it needs it urgently. The public men in Victoria are not without vision, and ambitious schemes are already in operation which will ensure the provision of power and water for a greatly increased population. At this time of centenary we confidently look to another Childers to found a second university, so that the old one may mature to its full greatness.

THE ANTIGENIC STIMULUS IN TRANSPLANTATION IMMUNITY

By Dr. R. E. BILLINGHAM*, Dr. L. BRENT and Prof. P. B. MEDAWAR, F.R.S.
University College, London

I. Introduction

'TRANSPLANTATION IMMUNITY' may be defined as the state of acquired resistance which leads to the destruction of homografts, that is, of grafts transplanted between two different members of the same species. The chemical nature of the substances that provoke it has so far defied analysis. It is widely believed, for want of clear evidence to the contrary, that only *living* cells can elicit transplantation immunity; and this belief appears to be upheld by the fact that an otherwise highly active suspension of living spleen cells or leucocytes loses its antigenic power after treatment in any of the following ways: heating to 48·5° C. for 20 min.; drying from the frozen state; or freezing and thawing three or four times. It will be shown here that the power of cells to elicit transplantation immunity depends neither upon their being alive nor upon thei structural integrity in any anatomical sense; and that the antigens responsible for skin transplantation immunity are certainly nuclear substances, and probably desoxyribonucleoproteins.

We have worked with mice of two strains (domesti sublines of strains *A* and *CBA*) acting as donors o recipients at will. These strains differ from each other by upwards of 10–15 genetically distinguishabl antigens which affect the survival of skin homografts The median survival times of skin homograft transplanted from *A* to *CBA* mice or vice versa ar as follows: $A \rightarrow CBA$, 11·0 ± 0·3 days; $CBA \rightarrow A$ 10·2 ± 0·3 days[2]. These figures refer to mic receiving homografts for the first time. A secon homograft, transplanted after the rejection of a first is destroyed within six days[3]: healing is weak vascular breakdown is virtually instantaneous, and the epithelium of the graft survives, for so long as it survives at all, in an entirely indolent state. This accelerated breakdown of 'second stage' homografts has been made the basis of a simple direct test for the existence of a state of immunity or sensitivity. First, mice are injected with the preparations that are to be examined for their antigenic power; then, three to five days later, they are grafted with skin of the same genetic origin as the substances under test. The homografts are inspected six days after their transplantation. Complete or advanced breakdown by the sixth day reveals the existence of a powerful state of immunity, for a normal homograft of six days standing is soundly healed, fully surviving, well vascularized, and exuberantly hyperplastic.

---

* Research Fellow of the British Empire Cancer Campaign.

The problem, then, has been to find out the source and nature of the substances which, injected into mice beforehand, cause skin homografts to break down about twice as rapidly as would otherwise have been the case.

An analysis making use of the principle of immunological tolerance had already shown that the antigens responsible for skin transplantation immunity are fully represented in all the living tissues of a single individual[4]. It was therefore not necessary to seek in skin itself the antigens which incite immunity against skin homografts. Most of our work has been done with splenic (wholly mesenchymal) and kidney (almost wholly epithelial) cells. Moreover, advantage has at all times been taken of the fact that the members of a single highly inbred strain of mice are for most practical purposes antigenically equivalent[5], so that (for example) the spleens or kidneys of a dozen *A*-line mice may be used as a source of antigens, and skin homografts from still other *A*-line mice may be used for testing for any state of immunity which those antigens might have provoked. The technique of skin grafting and of scoring grafts for their degree of survival has been described elsewhere[3].

2. Immunity caused by Disintegrated Cells

Spleen cells totally disrupted by ultrasonic irradiation in any of the following media were found to be powerfully antigenic: (*a*) buffered normal saline (0·15*M* sodium chloride, 0·001*M* phosphate buffer, *p*H 7·4); (*b*) normal citrate saline (0·135*M* sodium chloride, 0·015*M* trisodium citrate adjusted with citric acid to *p*H 7·4); (*c*) isotonic sucrose, 0·29*M*; and (*d*) water.

Cell suspensions were made by dividing clean, freshly removed *A* or *CBA* spleens (mean weights 112 mgm. and 78 mgm. respectively) into three or four parts and expressing the pulp through a fine-meshed stainless steel sieve by gentle but firm pressure with a flat-ended glass pestle. Connective tissue was retained by the sieve, and the larger cell clumps in the expressed pulp were broken up by sucking them in and out of a pipette. The mean cell yield was 221 m (m $= 10^6$) per 100 mgm. wet weight of spleen[6], a figure which includes naked nuclei as well as whole cells, because even quite gentle manipulation with a pipette will cause upwards of 20 per cent of spleen cells to be stripped of cytoplasm. In media lacking calcium ions this can be a minor nuisance, because with anything but the most gentle handling some of the cells are trapped and lost in fibrous clots caused by nuclear disintegration.

Cells to be disintegrated in media *a* or *b* were expressed into those media, washed by two or three centrifugations at low speeds, and resuspended to a final concentration of 100–200 m./ml. Cells ultimately to be resuspended and disintegrated in isotonic sucrose (*c*) were expressed into and washed in isotonic sucrose – calcium chloride (see below). The handling of cells to be extracted in distilled water is described under sub-heading 6.

For disintegration, aliquot volumes of 2·5–3·0 ml. were loaded into siliconed glass tubes (internal bore 10 mm., thickness 1 mm.) and held obliquely in the jet arising from a 340 kc./s. crystal transducer housed in transformer oil. Although longer and stronger exposures were admissible, it proved sufficient to expose each tube for 30–40 sec. to a nominal acoustic power output of 7·5 W./cm.^{2} (applied voltage 0·75 kV.)[7]. Latterly we have used a 50-W. 20-kc./s. transducer of the magnetostrictive type: the flat end of a parallel and vertically held half wave-length stub, coupled to the transducer, was applied to the surface of a 6–7 ml. volume of the suspension under treatment. 45–60 sec. exposure sufficed, provided that the exposure vessel was not more than 2–3 mm. wider than the stub. It will be noticed that these exposures fall very far short of what is necessary to disrupt bacterial cells[8].

Cells disintegrated in normal saline or normal citrate saline were broken into fine fibres of nuclear origin, interspersed with cytoplasmic matter, red-cell debris, etc. Antigenic activity was confined to the heavy insoluble fibrous fraction, which could be cleared of cytoplasmic and soluble matter by two or three sedimentations on the centrifuge at low speeds. In isotonic sucrose the cells were broken into very small round particles the smaller of which were not sedimentable by ordinary centrifugal forces. The antigenic activity of such a preparation was only just perceptibly reduced by centrifugation at 2,100 *g* for 20 min., that is, by exposure to more than twice the centrifugal force which, in less than half the time, would have sufficed to clear all whole cells or intact nuclei from a medium of this specific gravity; nor could the antigenic matter contained within a column 2 cm. deep be wholly sedimented by centrifugation at 11,000 *g* for 10 min.—an observation singly sufficient to dispel any idea that the antigenic activity of these 'particulate' preparations was due to contamination by whole nuclei or undisrupted cells. The specially important properties of the solutions formed by disintegrating cells in water are discussed under sub-heading 6.

Preparations made in media *a* to *d* were of about equal potency; the dosage (in cell equivalents) required to elicit violent immunity, such that a skin homograft transplanted three to five days after their injection would be destroyed within six days, was about 150–200 m per mouse. These experiments showed that transplantation immunity could be provoked by totally disrupted cells, but they gave no direct anatomical evidence of whereabouts in the cells the antigenic substances were to be found.

3. Location of the Antigens: Nucleus or Cytoplasm

Preparation of nuclei from spleen or thymus cells. Nuclei may be separated from spleen or thymus cells or leucocytes by fractional centrifugation after exposure to ultrasound in media containing calcium ions, namely: Ringer phosphate (containing 0·0028*M* calcium chloride, 0·0025*M* magnesium chloride, 0·001*M* phosphate buffer *p*H 7·4) or isotonic sucrose –

calcium chloride (0·0018M calcium chloride[9]). Cell suspensions prepared by the use of a sieve were washed two or three times by spinning at low speeds and then exposed to ultrasound of the intensity and duration described above. The nuclei were then separated by the use of barely sufficient centrifugal forces: two or three successive spins for 8 min. each at forces ranging from 200 to 700 g (for Ringer phosphate) or from 300 to 1,000 g (for sucrose–calcium chloride) down a fluid column height of 8–10 cm. would clear 2,000–4,000 m nuclei of visible cytoplasmic matter. The final preparation consisted of clean nuclei mixed with fibres of approximately the same specific gravity which could be shown to be artefacts of nuclear origin. Because of losses during exposure to ultrasound and the washes that preceded and followed it, only some 40 per cent of the original cells could be recovered as whole nuclei (mean yield 88 m/100 mgm. spleen). This yield could be improved by cutting down the time or intensity of exposure, but only at the proportionately increasing risk of allowing some nuclei to retain a cytoplasmic sheath. Unduly prolonged exposures reduced the yield of nuclei and increased the proportion of nuclear fibres.

Nuclei from kidney cells. Nuclei may be harvested from kidney cells by the judicious use of a high-speed blender. Clean decapsulated kidneys were cut into small pieces and washed in normal citrate saline. The pieces were then immersed in Ringer phosphate and exposed in a 100-ml. 'Vortex' flask to the action of an M.S.E. blender for 3–3½ min. at approximately 10,000 r.p.m. At this stage the preparation contained free nuclei, red cells, large quantities of cytoplasmic matter, and a multitude of short lengths of kidney tubules, but *isolated* living cells were extremely rare. The tubule segments were removed by repeated filtrations (if necessary, as many as fifteen) through a 3-cm.-deep column of loosely packed, well-rinsed glass wool; to avoid too great a loss of nuclei, not more than two filters were used. The nuclei in the filtrates were concentrated, and freed so far as possible from cytoplasmic matter, by four successive fractional centrifugations at low speeds. The final preparations contained nuclei together with about one-tenth their number of red cells, and they were appreciably contaminated by larger cytoplasmic particles and any agglutinates of smaller particles that may have settled with them. The presence of nuclear fibres, usually coinciding with an absence of red cells, was a sign that blending had been unduly fierce or prolonged. The nuclear yield was variable, but more than half our preparations fell within a modal class of 20–30 m per kidney. A greater yield is not to be expected, for the essence of this technique is that kidney tubules should *not* be cut up into cell-sized fragments. The nuclei are presumably extracted from the tubules by cavitational forces.

Test for the presence of intact cells. One ml. of a suspension containing 10–50 m nuclei in Ringer phosphate was exposed to the action of 0·01–0·10 mgm. trypsin for about 20 min. at room temperature. Naked nuclei are extraordinarily vulnerable to the action of trypsin; intact cells may therefore be spun down and looked for microscopically. Twelve and nine such tests on separate preparations of spleen and kidney nuclei revealed the presence of intact cells in three specimens and in one specimen respectively, but the degree of contamination could not, at the extreme, have exceeded 0·1 per cent. As a significant source of error, contamination of nuclei by living cells may be disregarded.

Preparation of cytoplasmic matter. It did not prove feasible to prepare a concentrated suspension of spleen cell cytoplasm uncontaminated by fine fibres of nuclear origin; but cytoplasmic particles have been prepared from kidney and liver by orthodox methods using isotonic sucrose[10] or normal saline as diluents. Having cleared the preparations of nuclei or nuclear matter, suspensions consisting predominantly of large or of small cytoplasmic particles were prepared by the use of moderate (5–8,000 g) or of high (25–40,000 g) centrifugal forces.

Location of antigenic substances. The substances which elicit skin transplantation immunity are exclusively confined to the nuclei of cells: preparations of kidney or liver cytoplasm (whether of larger or smaller particles, in high or in low dosages) were totally inactive. Indeed, in so far as they had any effect at all in the concentrations at which they were used, it was to reduce the homograft reaction below its normal level of intensity. Very highly concentrated suspensions of the scanty cytoplasm of spleen cells have occasionally been found to exercise the feeblest perceptible antigenic action, presumably caused by the fine nuclear fibres with which such preparations have invariably been contaminated.

4. Properties of Nuclei

A nuclear dosage of 100 m per mouse is more than sufficient to cause the total breakdown of a test homograft within six days of its transplantation; 25 m/mouse is an appreciably active dose. Under the same conditions of administration, 100 m nuclei are equivalent to about 5 m dissociated living cells. It is convenient to inject nuclei intraperitoneally at a concentration of 100 m/ml.; the intravenous route is at least as effective, but the subcutaneous route is much less satisfactory.

The injection of mice with nuclei or nuclear derivatives originating from other members of their own strain had no discernible effect upon their immunological responses.

Nuclei are unstable, and although we have not examined the consequences of doing otherwise, we have always prepared and kept nuclei in chilled media. Unlike living cells, nuclei could not be stored overnight in a balanced saline medium at 3°–5° C. without losing all but a small fraction of their antigenic power. The antigenic activity of nuclei or of totally disintegrated cells was reduced beyond a perceptible level of intensity by any of the following treatments: heating to 48·5° C. for 20 min., drying from the frozen state, or freezing and thawing three times. (Nuclei suspended in sucrose – calcium chloride were weakly protected against the damaging effects of these treatments.) With this evidence of instability it is not surprising that, in the past, antigenic activity should have been regarded as the prerogative of living cells. None of the treatments just described, except freezing and thawing in a salty medium, caused gross anatomical damage to the nuclei; the mere appearance of nuclei under the microscope is a remarkably poor guide to their antigenic power.

It was our normal practice to transplant test homografts of skin 3–5 days after the injection of the substances which were being examined for their antigenic power. A delay of 15 days allowed the state of immunity to become significantly weaker, and a delay of 30 days allowed it to fall to a level that was sometimes inappreciable in our test system.

The immunity produced by 'dead' preparations is therefore of much shorter tenure than that produced by 'solid' living grafts, such as skin homografts themselves[3]; we have yet to examine the duration of the immunity produced by the intraperitoneal injection of equivalent doses of dissociated living cells.

We have not yet succeeded in making active nuclear or disintegrated preparations from embryonic tissue. Yet there can be little doubt that the antigenic substances are fully developed long before birth, for the injection of so few as 5–10 m cells from 11½–12½ day mouse embryos caused the total breakdown, within six days, of test homografts of skin transplanted three days later. (The embryos were at a stage of development about equivalent to that of a 3 to 4-day chick.) It is known that, of the nine days that passed between the injection of the embryonic cells and the final scoring of the test homografts, about six days are required for the machinery of immunization to go into action and take effect; in the remaining balance of time, about three days, it is scarcely possible that the embryonic cells injected into adult mice should have advanced to the stage of development not normally achieved until birth. We may therefore take it that the transplantation antigens in mice are fully developed well before birth.

5. Action of Enzymes on Nuclei

Our study of the action of enzymes on nuclei has been complicated by their instability to mere incubation in 'physiological' media for 60 min. at 37° C. With rare and still unexplained exceptions, however, spleen nuclei, or the clean nuclear fibres prepared by the direct disintegration of spleen cells in normal citrate saline (sub-heading 2), were stable to 60-min. incubation in Ringer phosphate or Ringer bicarbonate (0·015*M* sodium bicarbonate, 0·001*M* disodium hydrogen phosphate) over the *p*H range 6·8–7·4; incubation at *p*H 5·5 (0·1*M* acetate buffer, 0·10*M* sodium chloride) or at *p*H 6·0–6·2 (phosphate buffer) was damaging but not totally destructive. On the other hand, kidney and thymus nuclei have given exasperatingly variable results, antigenic activity being sometimes lost after only 30-min. incubation. (This does not apply to kidney nuclei incubated with trypsin: see below.) The incubation of clean spleen nuclei deliberately contaminated with heavy inocula of kidney cytoplasm or red cells showed that these contaminants of kidney nuclear preparations were not to be blamed for their instability. We believed at one time that magnesium ions might be harmful—it was thought necessary, in certain experiments with desoxyribonuclease, to raise the concentration of magnesium chloride from 0·0025*M* to 0·10 or 0·0125*M*—but later experiments showed that this could not have been the whole explanation. The cause of the instability of kidney nuclei therefore remains obscure; if it is of enzymic origin, the enzymes must be presumed to be intranuclear.

For these reasons, our critical tests of the action of ribonuclease and desoxyribonuclease were made on spleen nuclei.

Ribonuclease. The incubation of spleen nuclei 100 m/ml. for 60 min. at 37° C. with ribonuclease 0·1 mgm./ml. in Ringer phosphate had no perceptible effect on their antigenic power; nor did the deliberate contamination of spleen nuclei with kidney cytoplasmic particles cause them to become vulnerable to the action of ribonuclease.

Trypsin. The gross anatomical action of trypsin on naked nuclei suspended in Ringer phosphate was spectacular: their membranes were disrupted almost instantly, and within three or four minutes at room temperature the preparation passed through a rigid fibro-gelatinous phase to form a largely clarified but only moderately viscous solution containing small quantities of miscellaneous debris in suspension.

The tryptic digestion of spleen or kidney nuclei (100 m/ml.; trypsin 0·1 mgm./ml.) in Ringer phosphate did not destroy and did not as a rule perceptibly impair their antigenic power; moreover, the serial sampling of digests in which the action of the enzyme had been stopped by adding trypsin inhibitor after 10, 20, 40 and 60 min. revealed no progressive deterioration as incubation went on. It should be observed, however, that this resistance to tryptic digestion was true *only* of nuclei prepared in the calcium-containing media which we have invariably used. Tryptic digestion of the nuclear fibres produced by the direct disintegration of spleen cells in normal citrate saline led to the formation of an almost unmanageably viscous solution with little or no antigenic power.

Desoxyribonuclease. Spleen nuclei 50 m/ml. were incubated for 60 min. at 37° C. with desoxyribonuclease 0·1 mgm./ml. in Ringer bicarbonate at a *p*H maintained between 6·8 and 7·2 throughout. After incubation, the nuclei, now translucent and grossly contracted, were spun down, resuspended in half the original volume of fluid, and injected intraperitoneally at a dosage of 1·0 ml. (100 m nuclei) per mouse. Under these conditions the antigenic power of the nuclei was completely or all but completely destroyed; control nuclei, receiving exactly parallel treatment in media lacking desoxyribonuclease, retained their antigenic power. Three points deserve special mention: (*a*) Ringer bicarbonate was used for these experiments because the weak buffer of Ringer phosphate could not prevent the *p*H of the incubation medium from falling precipitously to 6·2 or 6·4, that is, to a damaging level of acidity; (*b*) raising the concentration of magnesium chloride from 0·0025*M* to 0·0125*M* was not advantageous and might have been harmful; and (*c*) the use of lower concentrations of desoxyribonuclease or higher dosages of injected nuclei obscured the otherwise very sharp distinction between nuclei treated with desoxyribonuclease and their controls.

6. Solubility of the Antigens

It is implicit in all our methods of preparation that the antigenic substances, as they occur in their native form in nuclei or nuclear fibres, are insoluble in salt solutions of physiological strength (about 0·15*M*). The present section, an interim report on experiments still in progress, deals with their solubility in water and in strong solutions of salt.

Solubility in water. Spleen cells were prepared for aqueous dissolution as follows. The cells were expressed into, and washed in, buffered normal saline, and the spun sediment was resuspended in normal saline, to which three volumes of water were then added. The osmotically swollen cells were spun down, the pink supernatant fluid was rejected, and the somewhat gelatinous sediment was worked up in water with a coarse pipette. This aqueous suspension was exposed to ultrasound for 60 sec., whereupon most of the substance of the cells passed into a faintly opalescent and only moderately viscous solution. Matter in suspension was removed by centrifugation at 2,000 *g*. The supernatant fluid, injected in a dosage equivalent to 250 mgm. fresh splenic tissue per mouse, was highly active. When sodium chloride was added to restore its concentration to $0 \cdot 15M$, the bulky precipitate so formed was almost completely inactive: the supernatant fluid retained nearly all the antigenic power of the original solution. When, however, calcium chloride was added to bring its final concentration to only $0 \cdot 0025M$, the precipitate contained much the greater part of the antigenic matter, though some still remained in the supernatant fluid. It is evident, therefore, that the precipitates formed by adding sodium chloride and calcium chloride to aqueous cellular solutions have different properties. The precipitate formed upon the addition of calcium chloride is insoluble in water[11]; so also are nuclei prepared, as ours have been, in calcium-containing media.

We have had less satisfactory results with aqueous extracts of the washed nuclear fraction of kidney-cell disintegrates, prepared by a variant of the methods reintroduced by Stern[12].

Aqueous solutions clarified by centrifugation at 25,000 *g* for 30 min. are antigenically inactive, although they still contain matter precipitable by the addition of sodium chloride or calcium chloride.

Solubility in strong salt solutions. The antigenic power of nuclei prepared in calcium-containing media was reduced to about 25 per cent of its original value by extraction in molar salt solution; it could be completely abolished by prolonged extraction in $2M$ sodium chloride. In this sense, which is subject to obvious reservations, the antigens may be said to be soluble in strong solutions of salt. When $2M$ salt extracts of nuclei were clarified by centrifugation at 25,000 *g* for 30 min. and then diluted with 10 vol. water, the histone nucleate fibres so formed were found to be totally inactive, whether injected intraperitoneally or intravenously, or in their original or in a finely divided state. The same was true of the much more highly fibrous preparations of histone nucleate made from nuclear fractions which had at no time been exposed to bivalent metallic ions. Histone nucleate fibres of either origin were very rapidly digested by trypsin[13] to form immensely viscous solutions containing protein cleavage products and the sodium salts of desoxyribonucleic acids. Injected in high concentrations, before or after precipitation with ethanol, these crude preparations slightly but perceptibly impaired the homograft reaction, in the sense that test homografts transplanted on the same occasion (or two days beforehand, or three to nine days later) survived slightly longer than on normal mice. In lower dosages the fresh crude digests have repeatedly but not consistently been found to exercise an immunizing action of marginal intensity. In three experiments out of four, however, nuclei first exhausted by salt extraction and then mixed with crude DNA-containing digests blocked with trypsin inhibitor produced an immunity about equal to that elicited by 25 m fresh nuclei[14].

7. Nature of the Antigenic Substances

The antigens responsible for skin transplantation immunity in homografts exchanged between *A* and *CBA* mice comprise at least 10–15 genetically distinguishable substances[1]. They are wholly confined to the nuclei of cells. In their native form they are insoluble in physiological ($0 \cdot 15M$) salt solutions, but they are soluble in water, and may be precipitated therefrom by the addition of calcium chloride. The antigenic activity of nuclei can be weakened by extraction in *M* sodium chloride solution and abolished by extraction in $2M$ sodium chloride. The antigens are destroyed by digestion with desoxyribonuclease but not by digestion with ribonuclease or (under the conditions described in the text) with trypsin. They are highly unstable: in salty media, though somewhat less effectively in sucrose solutions, they are destroyed by freezing and thawing, by drying from the frozen state, and by heating to 48·5° C.

Three other properties of the antigens should be taken into consideration before passing judgment on their chemical nature: (*a*) an analysis based on the principle of immunological tolerance[4] has shown that the antigens responsible for skin transplantation immunity, so far from being peculiar to skin, are uniformly represented in all the living tissues of a single individual; (*b*) although living whole blood can elicit skin transplantation immunity (or tolerance[4]), its power to do so resides in the leucocyte fraction and is lacking from red cells, plasma and platelets[15]. (Platelets are of cytoplasmic origin and contain no desoxyribonucleic acid[16].) Finally, (*c*), the antigens are developed well before birth.

So far as we are aware, only one hypothesis can accommodate these findings: that the antigenic substances responsible for skin transplantation immunity are desoxyribonucleoproteins endowed with antigenic and therefore with genetic specificity. This hypothesis is made *likely* by our evidence, but the evidence falls short of proof. In particular, the properties of aqueous solutions of the antigenic substances, and of the precipitates formed from them by adding sodium chloride and calcium chloride, require further investigation. (It should not be forgotten that these aqueous solutions, particularly those prepared by ultrasonic methods, may be quite extensively degraded[17].)

If the antigens are indeed desoxyribonucleoproteins, they are almost certainly not, or not merely, nucleohistones. It is not, of course, to be expected that the genetically specific structure of a nucleoprotein should be even approximately reproduced when histone chloride and the sodium salts of desoxyribonucleic acids reassociate to form histone nucleate after diluting their solutions in strong salt[12,13,18]. On the other hand, we were surprised to find that the nucleohistone formed by adding sodium chloride in $0 \cdot 15M$ concentration to an antigenically active aqueous solution was itself inactive. The precipitate formed by adding calcium chloride in a concentration of $0 \cdot 0025M$ was strongly active, and the importance of the calcium ion made itself apparent in other ways; for example, in making the native nuclear antigens (*a*) stable to tryptic digestion, and (*b*) partly though not completely resistant to extraction by molar salt solution. The physical instability of the antigens suggests lipoprotein attachments, and it may well be, as several authors have suggested, that the nucleic acid is attached not merely to histone but also to the residual lipoid-containing 'acid' proteins of the nucleus as well[19]—an attachment in which bivalent metallic ions could well play an important part, for calcium[19] and magnesium[11] are both present.

There are well-recognized theoretical reasons for believing that the genetic and antigenic specificity of a nucleoprotein should reside in the desoxyribonucleic acid moiety, and in due course we hope to find out for certain whether or not this is really so. For this purpose it will clearly be necessary to devise some method for recombining desoxyribonucleic acid with nuclear protein which is much more efficient and reproducible than that described under sub-heading 6. It would be idle to discuss the origin of the weak antigenic action sometimes exercised by crude digests of histone nucleate fibres containing desoxyribonucleic acid until the possibility that it is due to desoxyribonucleic acid itself can be confirmed. At present it seems more likely to be due to the presence of small quantities of undissociated nucleoprotein—if indeed it is not due to substances of some altogether different kind.

Naked nuclei are only one-fifth to one-tenth as active as living cells in provoking transplantation immunity, and aqueous solutions of the antigens are weaker still. Part of the difference, perhaps a large part, can be attributed to the fact that they must be specially vulnerable to the endogenous desoxyribonucleases of the mice into which they are injected.

In view of the possibility that the antigenic substances are desoxyribonucleoproteins, we attach special importance to the experiments which have led us to believe that they are continually emitted by normal living cells[4].

8. Bearing on the Immunology of Transplantation

One important, if perhaps merely apparent, inconsistency between our work and that of others must now be resolved. It is known from a great wealth of genetical evidence that the transplantation antigens of an individual mouse comprise a multiplicity of substances which are intimately gene-controlled[20]. Some of the more important 'histocompatibility genes' which have been identified by genetical methods are already known from the pioneer work of Gorer[21] to determine a special system of iso-antigenic substances, hereafter '*H*-antigens' for short. *H*-antigens do not elicit skin transplantation immunity, and they are physically quite distinct from the nuclear antigens which we have just described. They are present in red cells and in cytoplasm; in mice, they are not formed until after birth[22]; and they are comparatively stable: lyophilized tissues, for example, are rich in *H*-antigens, though they do not elicit skin transplantation immunity. *H*-antigens are recognized and serologically labelled by their power to elicit the formation of orthodox serum iso-antibodies which can agglutinate homologous red cells, but there is clear evidence that these antibodies are not the effectors of transplantation immunity, at least of 'solid' grafts[23]. (It should be added that Bollag[24] has identified a system of iso-antigens in rabbits by purely serological methods. They cannot yet be classified with certainty; but their distribution, stability and solubility make it quite possible that they are nucleoproteins.)

The apparent paradox, then, is this: that the same histocompatibility alleles determine the formation *both* of the cytoplasmic *H*-antigens *and* of the nuclear antigens that are the prime movers in transplantation immunity. We can therefore only suppose that the two classes of antigens stand to each other in the relationship of secondary and immediate gene products; indeed, if our interpretation of their chemical nature is correct, the nuclear antigens consist of chromosomal matter. Certain questions suggest themselves immediately. Can the nuclear antigens elicit the formation of serum antibodies of the same kind as those produced by *H*-antigens, or, if not, can they specifically absorb the serum antibodies which *H*-antigens have formed? Again, how does it come about that homografts killed by, for example, lyophilization, and incapable of causing transplantation immunity, may yet elicit a brisk inflammatory response when implanted into animals which have been immunized beforehand by living homologous cells?[25] These and other questions[26] belong to the agenda of future research.

Summary

Cells totally disintegrated by ultrasonic irradiation retain their power to elicit skin transplantation immunity in mice. The substances responsible for this property reside wholly in the nuclei of cells, and are developed well before birth. They are inactivated by lyophilization, by freezing and thawing, and by heating to 48·5° C. They are inactivated by digestion with desoxyribonuclease but not with ribonuclease or, in certain stated circumstances, with trypsin. They are insoluble in salt solutions of physiological strength, but are soluble in water, from which they may be precipitated in an active form by the addition of calcium chloride; and they are extracted from nuclei by treatment with 2*M* sodium chloride solution. These facts, together with cognate evidence from other sources, make it probable that the antigens responsible for skin transplantation immunity are desoxyribonucleoproteins.

OBITUARIES

Sir Harold Scott, K.C.M.G.

Sir Harold Scott, who died at Braintree on August 6, shortly after his eighty-second birthday, was widely known as a pathologist, a historian of tropical medicine, and an editor. After taking medical qualifications in 1897, he served in the South African War, returned to England and entered general practice and then went to Jamaica as Government pathologist. The First World War brought him once more into the R.A.M.C., and after its conclusion he became Milner Research Fellow at the London School of Hygiene and Tropical Medicine, where he elucidated the life-history of *Hymenolepis*. He was then appointed Government pathologist at Hong Kong, retaining this post for several years until compelled to retire through ill-health. Later he became pathologist to the Zoological Society of London, medical secretary of the Colonial Medical Research Committee, and in turn assistant director (1930) and director (1935) of the Bureau of Hygiene and Tropical Diseases, until his retirement in 1942.

As a pathologist he published a large number of papers and monographs on tropical subjects—particularly on the vomiting sickness of Jamaica, the central neuritis of Jamaica, and on tuberculosis in man and lower animals (based on his experience in Hong Kong and at the Zoo). He wrote several books, including "Some Notable Epidemics" (1934), but his most important literary work was his great "History of Tropical Medicine" (1939), which has been recognized throughout the world as a masterpiece. At the Bureau of Hygiene and Tropical Diseases he edited the *Tropical Diseases Bulletin* and the *Bulletin of Hygiene*, and it was under his direction that the *Bulletin of War Medicine* was created. He was appointed C.M.G. in 1935 and K.C.M.G. in 1941.

Scott was for many years associated with the Royal Society of Tropical Medicine and Hygiene, of which, to his great pleasure, he was elected president in 1943.

One of his most outstanding characteristics was a capacity for hard, sustained and conscientious work. He was a man of high intelligence and quick decision, and he worked rapidly, leaving himself ample time for the voracious reading which was his chief relaxation. He was a great buyer of books on all kinds of subjects, and accumulated a large and varied library, particularly rich in historical works. He loved his canaries and budgerigar, and the animals at the Zoo, and this no doubt stimulated his interest in the immense subject of the animal reservoirs of human disease, so important in tropical medicine.

Scott was a delightful companion, full of humour, which on occasion could be pointed, but which was modified by a rather old-world courtesy. Physically he was slight, good-looking, and always immaculately dressed. He moved with ease and assurance among the leaders of his profession and made many friends. His first wife died in 1933; his second wife, Eileen Anne, daughter of the Rev. R. P. Prichard, survives him.

Charles Wilcocks

Dr. E. Leonard Gill

E. Leonard Gill died in Cape Town on July 5. He was born in Reigate and after attending a Friends school, entered Owens College, Manchester, graduating in 1899. He then became a member of the museum staff at Manchester and so gained experience in museum arts and management. Later, he became curator of the Hancock Museum, Newcastle upon Tyne. Here he was responsible for large, important collections of fossils, birds and marine invertebrates, as well as the general contents of an old-established natural history museum. The maintenance of this large building, very old-fashioned in its design and furnishing, also fell to him, and the funds of the Society which owned it were, even then, inadequate.

Gill served in the Friends Ambulance throughout the First World War, returning to the Museum, when he began to modernize some exhibits. In 1922 he accepted a post in the Royal Scottish Museum; but in 1924 he became director of the South African Museum, Cape Town.

In the seventeen years he spent in this post, Gill revolutionized the Museum; its size was nearly doubled, the exhibition galleries were modernized and enlarged, and the scope of the Museum was extended to cover not only important South African antiquities, but also some art collections. Gill wrote descriptive labels, in Africaans as well as English, which brought the Museum into much closer touch with the general public, and increased this contact by circulating specially made museum cases to schools.

Gill published a few useful papers on fossil fish; but his chief interest was in birds. On his first visit to the Museum in Cape Town, he found on his table a dead bird just picked up and brought in. On its leg was a ring which Gill himself had placed there at a nest in the Farne Islands. Gill found that there was no small cheap book about South African birds, so that it was impossible for any ordinary man to know them, and thus to observe them intelligently. Hence he wrote an inexpensive book with many small but admirable figures drawn by Gill himself and his artist sister. This book was most useful, not only in South Africa but even farther north, and it has gone through several editions.

Gill added to the general interest in natural history, by newspaper articles in Africaans as well as English, and by lecture talks. Also he founded the South African Ornithological Society, which recently celebrated its silver jubilee.

Gill was a man of unusual character, willing to take great trouble to help anybody, friendly and helpful to everyone.

D. M. S. Watson

Mr. John A. Marsh

Through the death of John Anderson Marsh, which occurred on July 1, the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) has lost a greatly valued chief technician who had given it his loyal service for more than forty-six years. Appointed to the Institute on its foundation in 1909, he then worked for its first director, Alexander Paine, and for Casimir Funk and Jack (later Sir Jack) Drummond, at that time engaged in investigations of the 'vitamines' and of the amino-acid composition of tumours, respectively. Under his later directors, Archibald Leitch and Sir Ernest Kennaway, he played an essential part in assisting their contributions in the field of chemical carcinogenesis, first in studies with coal-tar, and later in the great development of the cancer-producing hydrocarbons.

A man of wide interests and much kindliness, Marsh inspired friendship in all his colleagues, not least in the numerous workers from abroad whom he had helped over the years, and who mourn him equally with ourselves. He had seen great changes in research, and throughout his long service at all times embodied the true worth of the chief technician. Both for his unique contribution and for his personal qualities, he will be ever gratefully remembered by all who knew him.

ALEX. HADDOW

NEWS and VIEWS

New President of the British Association: Prof. P. M. S. Blackett, F.R.S.

AT the meeting of the General Committee of the British Association for the Advancement of Science held in Sheffield on August 29, Prof. P. M. S. Blackett was elected to succeed Sir Raymond Priestley as president. Prof. Blackett was born in 1897 and educated for the Navy at Osborne and Dartmouth. After war service during 1914–18 he studied at Cambridge, where he took Part I of the Mathematical Tripos and Part II of the Natural Sciences Tripos in physics. He then worked under Rutherford in the Cavendish Laboratory until 1933. From 1933 onwards he has been successively professor of physics at Birkbeck College, London, University of Manchester and the Imperial College of Science and Technology, London. He received a Royal Medal from the Royal Society in 1940 and was awarded a Nobel Prize in 1948.

Prof. Blackett and those working with him have made significant contributions to three main fields of physical discovery: the interaction with matter of fast particles from radioactive sources, the nature of the particles in the cosmic rays and the magnetism of the Earth. During 1921–31 he was chiefly occupied with the development and operation of automatic Wilson cloud chambers and their application to the precise measurement of the parameters involved in collisions between alpha-particles and atomic nuclei. By painstaking work he showed that very infrequent inelastic collisions with nitrogen produced the then unknown isotope oxygen-17 by the capture of the alpha-particle and the ejection of a proton. In this period also he verified, with Champion, the Mott theory of the wave-mechanical diffraction scattering of slow alpha-particles. From 1931 onwards he applied and extended the cloud chamber technique to the study of the collisions involved in the cosmic rays, establishing (with Occhialini) the existence of nearly equal numbers of positive and negative electrons. This confirmed Anderson's discovery of the positive electron a few months before and extended it by giving strong evidence for actual pair production. In addition, the 0·5-MeV. scattered gamma-rays were identified as arising from the annihilation of positive and negative electron pairs. With a large magnet and a new counter-controlled cloud chamber, Blackett and his colleagues proceeded to study in more detail the nature and the energy spectrum of cosmic ray particles. Much valuable work on cosmic ray showers was carried out under his direction, and he himself explained the negative temperature coefficient of the cosmic rays in terms of the decay of the μ-meson.

These detailed studies led to a discovery which opened up the entirely new field of 'strange' particles when Rochester and Butler in Blackett's laboratory in 1946 found the first neutral V-particles and in 1947 the first charged V-particles. The identification by the Manchester team of V^0 decay into a proton and a pion and of the probable division of a V^1 particle into two pions, together with the best determination to date of the life-times of V^0 and V^1 neutral particles, are outstanding further discoveries. These were made possible by Blackett's energetic action in moving the equipment to the observatory of the Pic du Midi. From 1947 onwards he interested himself in the possibility, originally discussed by Schuster, of a 'fundamental' connexion between the angular momentum of a large rotating body, such as the Earth, and its magnetic field. Although experiments conducted and suggested by him gave no support to this idea, the sensitive magnetometer designed for this work has been used by him and by Runcorn at Cambridge in remarkable studies of palæomagnetism which give promise of throwing new light on polar wandering and continental drift.

Chemistry in Swansea: Prof. C. H. Hassall

PROF. C. H. HASSALL, professor of chemistry in the University College of the West Indies, has been appointed to the chair of chemistry in University College, Swansea (University of Wales), in succession to Prof. C. W. Shoppee, who has accepted the chair of organic chemistry in the University of Sydney, New South Wales, Australia. Prof. Hassall graduated in the University of New Zealand in 1941 and after war service went with a senior studentship of the 1851 Exhibition to Cambridge, and carried out research in organic chemistry with Sir Alexander Todd. In 1948 he accepted the chair of chemistry in the young University College of the West Indies, where he has been responsible for building up a new department, involving the design of laboratories, recruitment of staff and the development of teaching and research. During this period he has also managed to visit Harvard, where he worked in Prof. R. B. Woodward's laboratory for a time, and a number of university departments and industrial research laboratories in England working on organic natural products. These activities explain in part the close links which Prof. Hassall has formed between his department and industry in the West Indies and with several pharmaceutical firms in Europe. He has served as the United Kingdom representative on the Caribbean Research Council and is a member of the advisory committee of the Institute of Social and Economic Research, Jamaica. His research work has been mainly in the field of the structural chemistry of organic compounds of biological activity such as steroids, polypeptides and antibiotics.

Weather Forecast Service in Britain by Telephone

THE automatic weather forecast service by telephone which came into operation in Britain at midnight on March 4 has been a great success. In the first month 561,377 calls were received from the public, a number far exceeding the number made to the London Forecast Office in any month; the number of calls to the Office during February was 17,128. This experience is similar to that in other countries. The number in the first month was probably boosted by mere curiosity, for the number of calls in July was 339,384. Clearly the automatic system provides an 'on demand' weather forecast service quite beyond the capacity of a forecast office answering direct inquiries. The mechanical arrangements of the forecasting service are described by W. R. Hanson in the July number of the *Meteorological Magazine*. The forecasts are prepared in the Meteorological Office and recorded on tape at telephone exchanges of the General Post Office. They do not, as has been the arrangement elsewhere, consist of the nearest applicable stock phrases, but are compiled to express the forecaster's opinion as nearly as possible within the limits of the time allowed—which must be at most 30 sec. The forecast can be revised at any time, and there is provision for automatic switching in of a second tape if the first breaks down and for keeping the service going during recording of a new forecast.

Nuclear Research Reactor at the Massachusetts Institute of Technology

THE National Science Foundation, Washington, D.C., has made a grant of 500,000 dollars to the Massachusetts Institute of Technology towards the construction of a nuclear research reactor, plans for which have been under way since 1952. The remaining cost, which will be at least 2,000,000 dollars, will be borne out of funds raised by Massachusetts Institute of Technology alumni and by a grant from the Rockefeller Foundation. The reactor will use enriched uranium-235 as fuel, and will be cooled and moderated by heavy water. The main core will be surrounded by a graphite reflector and housed in an air-tight building with a dome-shaped roof, the site for which is 136 Albany Street, Cambridge, Mass. Construction is already under way and is expected to be completed in the autumn of next year. The design of the reactor has been chosen to give the maximum degree of safety together with facilities for a large number of experiments in nuclear physics, which will be the principal function of the reactor. However, it will also be made available for research in solid-state physics, food technology, genetics, chemical and nuclear engineering, and medicine. The whole project is under the general direction of Dr. Manson Benedict, professor of nuclear engineering in the Department of Chemical Engineering. Dr. T. J. Thompson, formerly chairman of the Design and Construction Committee of the Omega West Reactor of the Los Alamos Scientific Laboratory, has designed the reactor and will supervise its construction.

Gwerin : a New Journal of Folk-lore

A NEW journal of folk-lore, *Gwerin* (Welsh for 'folk'), has been inaugurated, and the first number appeared in June. The forty-eight pages of the number contain three main articles, the first on how certain straw-rope granaries near Cork are made, a second on some Hebridean traditions, and a third on the manufacture in Suffolk of wooden rakes and scythe sticks. It is not easy to make descriptions of how things are constructed readily intelligible, and it is virtually impossible to make them exciting. Therefore, if the new journal is to survive, one might suggest that plenty of room should be set aside for the legend and fairy-tale side of the subject, which always has a great appeal. But constructional descriptions should be recorded somewhere even if only the accounts are deposited in some recognized museum. The straw-rope granaries make an interesting article, and it must be news to many that rakes and scythe sticks were a special feature of rural industries in Cambridgeshire and the neighbouring counties of Suffolk and Bedfordshire. It is good to know that story-telling and traditional music are still popular in the Hebrides and that they have not been ousted by the modern, 'popular' entertainment that pours forth over the radio and television and from so many printing-presses and film studios. There is, indeed, room for a journal devoted to folk-lore, and all will wish the new venture every success.

Makers of Modern Science

THE series of ten articles, each devoted to a brief description of one of the great prime movers in the development of science, which appeared originally in *The Times Educational Supplement*, has now been reprinted and issued as an attractive booklet, entitled "Makers of Modern Science" (pp. 44+10 plates. London: The Times Publishing Co., Ltd., 1956; 2*s*. 6*d*.). Each article is accompanied by a full-page photograph of its subject. The aim of the contributors, present-day eminent men of science, is to write about their subjects in a way which would not appear absurdly elementary to specialists in science and yet which would not be too repellently difficult for specialists in humanities. It is hoped that the articles will act as a bridge of general conversation between arts men and scientists. Except for Louis Pasteur and Charles Darwin, the prime movers are physicists or chemists who laid the foundations for our present-day knowledge of the structure of matter and of the atom in particular—Galileo, Newton, Dalton, Faraday, Mendeleev, J. J. Thomson and Rutherford. The late Dr. Sherwood Taylor, who took a large part in the preparation of the series, contributes the article on Galileo, and this represents one of the last writings of this distinguished historian of science. Sir Lawrence Bragg is the author of the article on Faraday; Dr. Charles Singer on Pasteur; Prof. J. R. Partington on Mendeleev; Sir George Thomson on his father; and Prof. P. M. S. Blackett on Rutherford.

Basic Concepts and Methods of Psycho-analysis

THE centenary of Freud is commemorated in a recent number of the *British Journal for the Philosophy of Science*, which contains seven articles that attempt, with considerable though varying success, to clarify some of the basic concepts and methods of psychoanalysis. Two contributions state in very clear terms the theoretical and practical difficulties that arise from the over-determination of mental phenomena—that is, the fact that many of these data are explicable in terms of different, and incompatible, laws and hypotheses. Similar problems are, of course, encountered in other fields of science, so that this number of the *Journal* is of quite general interest.

Commonwealth Fund Fellowships for Advanced Study and Travel in the United States

A NUMBER of Commonwealth Fund fellowships are again being offered by the Commonwealth Fund, New York, to British subjects for study and travel in the United States. All expenses of travel, study and living will be met, with some adjustment of stipends for married men. The fellowships which are open to British men or women who have not previously worked or studied for more than a few months in the United States are in six categories as follows. *General:* twenty fellowships to graduates of universities in Great Britain or Northern Ireland; candidates must be available in London for interview in March 1957; age, 23–32; tenure, 12–21 months; applications by December 15. *Home Civil Service:* five fellowships to permanent members in the higher ranks of the Civil Service in Great Britain, three for the administrative grades and two for the scientific and professional grades; age, preferably less than 40; tenure, 9–15 months; applications by December 10. *Australian and New Zealand Civil Services:* five fellowships to Civil servants in the Governments of Australia and New Zealand; age, less than 40; tenure, 9–15 months; applications (to Dr. H. Carlyle Forster, Box 4079, Melbourne, and the Public Service Commission, Wellington, N.Z., respectively) by November 1. *Oversea Civil Service:* two fellowships to Civil servants in the Governments of British Colonies, Protectorates, and Trust Territories; age, less than 40; tenure, 9–15 months; applications by November 17. *Journalism:* three fellowships to journalists practising in Britain and engaged on the opinion-making or broadly editorial side of their profession; age, 23–35; tenure, 9–15 months; applications by December 31. *American Studies:* four fellowships to faculty members appointed to or holding posts in American studies in universities in Britain; candidates to be nominated by their universities; tenure, 4–15 months (these fellowships are not limited by previous study in the United States). Application forms and further information can be obtained through British universities or through Government departments, or from the Warden, Harkness House, 35 Portman Square, London, W.1.

Seventh International Astronautical Congress

THE Seventh International Astronautical Congress, sponsored this year by the Associazione Italiana Razzi (Piazza S. Bernardo n. 101, Rome, Italy), will be held in the Congress Palace, Rome, during September 17–22. A total of forty-two papers will be presented at the Congress, as follows: United States, 18, including six on the Vanguard satellite and related problems; Italy, 8; Germany and Austria, 4 each; Holland, 2; and Great Britain, Holland, Egypt, Poland, Sweden and Argentina, 1 each. Arrangements have been made for simultaneous translation service in Italian, French, English and German. Further information can be obtained from the British Interplanetary Society, 12 Bessborough Gardens, London, S.W.1.

Announcements

THE thirty-second meeting of the Australian and New Zealand Association for the Advancement of Science will be held in Dunedin, New Zealand, during January 16–23, 1957, under the presidency of Sir Macfarlane Burnet. Enrolment forms, to be completed by December 12, and further information can be obtained from the honorary local secretary, Prof. J. R. A. McMillan, Science House, 157 Gloucester Street, Sydney, N.S.W. Those seeking accommodation should complete the necessary form and return it by October 31 to Dr. R. E. Corbett, Department of Chemistry, University of Otago, Dunedin, N.I., N.Z.

THE Scottish Group of the Nutrition Society will hold a symposium in Dundee on September 29 on "Nutrition in Pregnancy". The papers to be read will deal with both human and animal nutrition. Those interested should write for further particulars to Dr. J. Davidson at the Rowett Research Institute, Bucksburn, Aberdeenshire.

THE fourth in the series of international conferences on Alpine meteorology will be held in Chamonix during September 17–19. The topics to be considered will be: precipitation in mountain areas; the types of weather in the Alpine region and their classification; radiation in mountain areas; and the bioclimatology of the Alps. Further information can be obtained from the Secretariat of the Congress at 72 rue Pasteur, Lyons, Rhône.

THE Textile Institute will hold a conference in Zurich during September 13–17 at which the subject of "Static Electricity in Textiles" will be discussed. This will be the second in the Institute's series of overseas conferences, and more than a hundred textile experts and scientists from Britain will join about the same number from other parts of Europe and from North America. Further information can be obtained from the Development Officer of the Textile Institute, 10 Blackfriars Street, Manchester 3.

A SYMPOSIUM on "Recent Studies in Yeast and their Significance in Industry", jointly arranged by the Dublin and District Section, the Microbiology Group and the Food Group of the Society of Chemical Industry, will be held in the Rupert Guinness Hall, St. James's Gate, Dublin, during September 17–19. The symposium will be open to non-members of the Society on payment of a registration fee of 25*s*. Further information can be obtained from Dr. A. K. Mills, Chemist's Laboratory, Arthur Guinness Son and Co. (Dublin), Ltd., St. James's Gate, Dublin.

THE Ford Foundation has given a grant of 400,000 dollars to the European Organization for Nuclear Research to help in strengthening co-operation in nuclear physics research, primarily with the United States and with other countries not members of the Organization. The grant is to be spent over five years and will be used mainly for enabling guest professors and young scientists to work in the Organization.

THE University of Padua is offering a Gabriella Zuccari scholarship of 300,000–600,000 lire for research of at least six months duration at the Zoological Station, Naples, during 1957. The scholarship is open to any person for research in zoology, comparative anatomy, physiology or embryology. Application forms, to be returned by October 31, can be obtained from the Administrative Director of the University of Padua.

THE report for 1955 of the Chemical Research Laboratory, Teddington (pp. 88+1 plate. London: H.M.S.O., 1956; 4*s*. net), contains an interesting survey of work carried out there. Some of the activities are linked with that of the United Kingdom Atomic Energy Authority and include the extraction of uranium and other metals, the separation of rare earths, and related problems. Other work is on the preparation of semi-conductors in a very pure state, paper chromatography, and the bacterial breakdown of aromatic substances available as waste-products.

ERRATUM. In the article entitled "The Neutrino" in *Nature* of September 1, p. 446, equation 7 should read:

$$\sigma = \left(\frac{G^2}{2\pi}\right)\left(\frac{\hbar}{mc}\right)^2\left(\frac{p}{mc}\right)^2\frac{1}{(v/c)}$$

APPLIED RESEARCH AND DEVELOPMENT WITHIN THE INDUSTRIAL GROUP OF THE U.K. ATOMIC ENERGY AUTHORITY

By L. ROTHERHAM* and DR. A. B. McINTOSH†
Industrial Group, U.K. Atomic Energy Authority

IN the United Kingdom Atomic Energy Authority, the Industrial Group is responsible for the design, construction and operation of plants for the production of fissile material and for the prototype power stations such as that at Calder Hall or Dounreay. It deals with sanctioned commitments dispersed at sites throughout the whole country, and has three main branches with clearly defined responsibilities, each under its own director. The design and construction of reactors and process plants are the responsibility of the Engineering Branch, and their operation and level of production are the business of the Operations Branch.

The Research and Development Branch deals with development work affecting the Industrial Group, and its laboratories are suitably related to geographically separated works sites. It is responsible for the removal of difficulties preventing full production in any part of a production plant, the development of works processes, the provision of information for the design of new plants and prototype reactors, and the longer-term studies arising from production and design. Close collaboration is maintained with the Research Establishment at Harwell, which undertakes part of the work.

The Branch has its administrative centre at the Industrial Group headquarters at Risley, where the headquarters of the Engineering and Operations Branches are also located. Continuous consultation is thus assured between the main centres of administration, finance, engineering and operations.

There are five Laboratories and, except for some specialized fields in which Harwell is responsible, these provide the development effort for all sanctioned construction projects. The Capenhurst Laboratories deal mainly with problems of an engineering nature, such as fluid flow and heat transfer. At Windscale, the Laboratories are largely devoted to radioactive chemistry, metallurgy and physics, arising from reactor problems at Windscale, Calder and Chapel Cross, and to the chemical problems of plutonium separation. Culcheth is responsible for the selection and development of reactor materials and for research work on the extraction of these if they are not commercially available. This is extended on a narrowed front at the Springfields Laboratory, which is responsible for the development of fuels and fuel elements. The new Laboratories at Dounreay are concerned with experimental reactor technology.

Planning and Progress of Applied Research

In the development of nuclear power there is necessarily a closer contact between scientists and engineers than in many well-established activities, because each new venture represents a major advance in technology. Applied research must be regarded as an essential complement to engineering and should be organized as such.

Both Engineering and Operations (or Works) Branches require the support of timely, authoritative and responsible scientific opinion to form the basis of major engineering and operational decisions. Decisions should not have to be made from the information nearest in character arising from a distantly related research problem. Investigations must aim at providing the precise information on the day it is required. It must be research applied to industrial needs and not pure research. Only applied research can be designed to influence commitments already made. The emphasis must always be on obtaining necessary techniques or data by a particular date. All work must therefore be planned and progressed in the same way as the Engineering Construction or Production Programmes to which it is linked.

The system of organization which has been developed begins with a study of work requirement aimed at providing the scientific personnel with a profitable programme of research and development. Such a programme, however, is no more than a declaration of intention. It must be integrated with a system of executive management which, in providing the machine to discharge the programme, preserves scientific integrity, and yet allows firm direction and control.

Many different and competing schemes may be judged as suitable for feasibility study, development or design, although restrictions may eventually be imposed due to limitations in available engineering effort. A widely dispersed research and development effort stretched over too many projects is less effective than a more concentrated attack on a narrow front. At the earliest possible stage responsible assessment must decide the most profitable direction for the application of the available applied research and development effort. The constant need for selecting only projects from which the greatest return will be obtained leads to the dual needs of strategic and tactical planning and to the development of two types of organization, functional and executive, each directly responsible to the director. The resolution of the separate points of view leads to the formulation of research policy which must conform to the overall policy of the Board of Management. The initiation, control and termination of all work necessary in the execution of this policy is effected by the wise use of delegated financial authority. The Director o Research is chairman of the Research Board formed for this purpose. The Secretary is the senior scientis in charge of central administration, and the members from the Branch are the heads of all the experimenta establishments and the chief scientists responsible for functional activities. Members from outside the Branch are the Directors of Administration, Engineering, Operations, Stores and Accounts and Technical Policy or sufficiently senior deputies.

---

* Director of Research and Development, U.K.A.E.A. (Industrial Group).

† Head of Culcheth Laboratories, U.K.A.E.A. (Industrial Group).

A body constituted in this way brings together a group of the most senior staff appropriate to consider the action arising from all matters affecting general and technical policy, organization and finance.

The procedure adopted is for a short paper to be prepared by one of the Research Board and circulated to other members prior to debate. On the Organization and Finance side, typical subjects under constant review are methods of reporting of work, training schemes, staff structures complements and accounting procedures. On the technical side the attitude to specific research projects is clarified by debate following presentation of papers from both functional and executive points of view.

Firm direction of experimental work to a policy is assured if control is exercised on capital and operational expenditures, staff recruitment and the requisitioning, initiation, progress and termination of work.

Annual Budgets

Each year the heads of experimental establishments submit to the Research Board estimates of their capital and operational expenses for the next financial year. A total is agreed for each and the collective budget is presented by the Director to the Board of Management for approval. Ultimate acceptance and voting of funds does not constitute authority to spend.

Each proposed item of expenditure beyond a small sum must be separately justified during the financial year. The Director of Research and Development has a delegated financial authority from the Board of Management which he ordinarily exercises through the Research Board. A lower authority is further delegated to each establishment head. Beyond the delegated authority, submission must be made to the Board of Management; but no proposal will go forward without prior discussion at and support of the Research Board.

A statement of running costs under separate cost headings is available for consideration at each meeting of the Research Board. These are issued by the Accounts Branch and show the actual budgeted expenditure for the period together with the recorded and budgeted cumulative total fraction of the year's expenditure. These statements are among the most important documents for laboratory management.

Requisition, Initiation and Review of Work

A sanction procedure has been carefully worked out and coupled with a formal system of work requisition and initiation. Where a large allocation of effort is involved which is equivalent to major operational expense, a formal justification must be made as a development proposal which will briefly detail the problems, methods of approach proposed, staff utilization and associated capital expenditure according to a timed programme of the work.

Each month the Research Board has before it a statement giving all jobs due for review or completion in that month. This includes a comparison of the estimated and the recorded labour expenditure and cost. Departures from the initial timed plan in the expenditure of labour or finance or in technical progress must be accounted for to the Board's satisfaction.

A progress statement on each job in the Branch Programme is made each two months, and opportunity is afforded each member of the Research Board to raise any question regarding the work. The collected progress statements, which give for each job the object of the work, the priority, estimated effort, starting and finishing dates, review dates and brief up-to-date progress statement are forwarded for the approval of the Board of Management. This document is unique in its value to chief engineers, works general managers, and all workers in the field.

Staff

The staff position in each laboratory is considered each month and curves show how recruitment in the Branch compares with that forecast. Recruitment campaigns or embargos are approved as a result. Other aspects discussed include recruitment difficulties in particular grades or non-uniformity in duties of grades from laboratory to laboratory.

Because there is a shortage of scientists, it has been an item of policy to take positive steps to ensure the most efficient use of every member by selecting the most rewarding items of research on which to utilize available effort. Such programming of work cannot do more than indicate directions for effort. It is for executive management to form a tactical plan to ensure that each member is suitably and wholly employed.

Survey of Competitive Demands

In many fields of modern engineering and works practice, as with atomic energy, highly specialized sciences either do or should form the basis of the activity.

A design project which may begin as an idea in the Research Branch, although initiated as a result of experience or inspiration in any of the branches, becomes a sanctioned commitment only after successful study of feasibility. Each commitment sanctioned requires planning to ensure that all facets are covered so that the target date is met. Formal or informal discussion of basic technical points on which key decisions are necessary usually leads to demand for scientific investigation. Such demands compete with one another, and it is a specialized study to assess the comparative weight which should be allowed for each.

All engineering and production programmes must be interpreted so that effort can be deployed in phase. Work performed out of phase denies effort to essential and relevant studies of the moment. This timing is vital in the later allocation of laboratory priorities.

The research programme can be designed to influence the trend of development. Responsible anticipation should lead to an endeavour to prepare for the future. Refinements or developments apparent at the research stage should receive consideration so that sufficient evidence may be available to justify development studies. The question "Where do we go next ?" is properly answered by the research programme.

Central Technical Administration

Closely planned activities, requiring prompt central administrative action, justify the existence of an Administration Group, to act as liaison with the main Administrative, Finance, Engineering and Operations Branches. Under a technical head, this is mainly a technical group distinct from professional or financial administrators. They are in a position to have a better appreciation of the needs of the

scientific staff and thus to act as a bridge between the main administration and the Branch.

The group collates the records supplied by all laboratories to form a master record of all effort in the Branch. These records of utilization of scientific and experimental effort are invaluable in the overall planning of work and in determining what commitments can be undertaken in the future.

The head of the Central Administration, as secretary of the Research Board, is responsible for the organizing of all business of the Research Board from the issuing of the agenda to the compilation of the minutes.

The Central Administration also has responsibility for all library and information services, although this does not extend further in the laboratories than ensuring uniformity of system. Much of the detail of methods used in the allocation and accounting of labour was worked out by the Central Administration.

Allocation of Responsibilities

The senior staff structure developed for the functional and executive control of applied research is shown in Fig. 1 in relation to the activities requiring development effort. Specific responsibilities carried by all members are integrated at the Research Board to result in agreed executive action. All bodies other than the Research Board are advisory, and all work arising from them must follow the formal Research Board sanction procedure. This is essential if firm control is to be maintained on the work of the experimental establishments. Fig. 2 shows the focal nature of the Research Board and the parts played by both functional and executive organizations in the representation of the Branch. Normally executive representation is required only for sanctioned commitments involving major effort.

The essential functional responsibility is to prepare a strategic plan linked to the overall scheme of development approved by the Board of Management, and then to co-ordinate all research and development effort according to that plan. Although tied to key dates for five to ten years, this must be sufficiently fluid to allow revision at, say, yearly intervals according to changing emphasis and the impact of experience. Promising researches must be related to an intimate knowledge of works practice and industrial development. Interchange of views and discussion on technical research problems must be arranged.

In general, sanctioned commitments always have the higher priority, but appreciable effort must be devoted to work in the earliest stages of feasibility and research studies. Such work suffers if done in isolation because the benefits conferred by expert consultants is lost. The findings of the work must be made known to all who can assist in assessing the directions in which they may be exploited. This is a functional responsibility, and staff with such duties should have direct access to the scientific workers at all levels in the laboratories so that the most up-to-date picture can always be presented. When the activity is large enough, it is convenient to divide the functional responsibilities into chemistry and chemical engineering, physics and engineering, and metallurgy, each under a senior member of the staff or chief scientist directly responsible to the Director of Research and Development.

The officer in charge of functional work should be of senior status, so that he has at least parity in discussion with chief engineers, works general managers, and heads of experimental establishments. Because of the difficulties in the comparative assessment of competing demands, a man of mature ability and experience able to take a detached view is essential for this work.

By collaboration with all parties who have an interest and can express a responsible opinion, the chief scientists advise on the forward forecast of research and development. Existing engineering commitments will have higher priority, and experi-

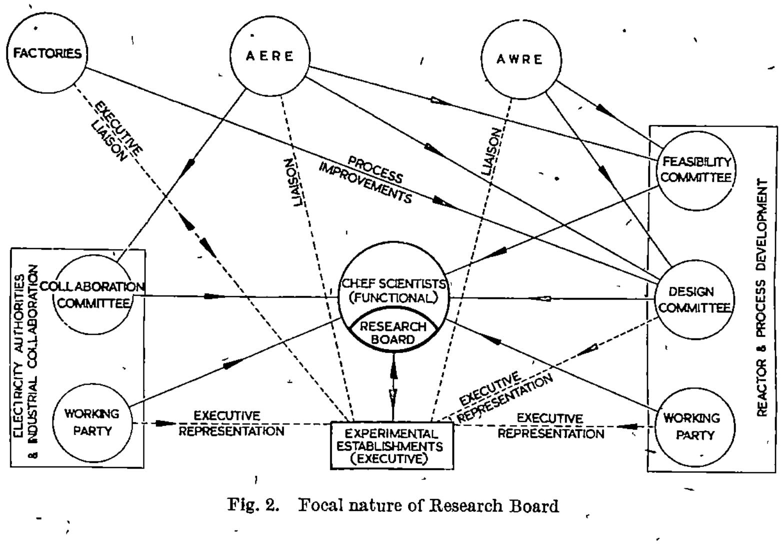

Fig. 2. Focal nature of Research Board

ence in the laboratories may suggest modifications. The several views are unified at the Research Board. After it is agreed, the strategic plan can be detailed, based on the accumulated records of work which should be compiled at the laboratories and from which the effort and cost of investigations similar in nature can be deduced.

The value of such a strategic plan is that it should show realistically how many development projects can be dealt with within existing strength, when key decisions are necessary related to overall construction or production plans, the expected utilization of labour and the possible need for recruitment. After formal executive approval, it should be distributed to senior members of other branches to apprise them of the extent of effort applied on their behalf and to allow the opportunity for further discussion on over-all policy. Executively, it provides the key to effective utilization of effort.

Where a number of experimental establishments is involved, an important functional responsibility is to ensure that all work is co-ordinated according to the agreed plan, and all but necessary duplication avoided. Constant discussion with the experimental workers should mean that new findings are applied expeditiously even before publication.

Where facilities to cater for some aspect do not exist anywhere in the organization, arrangement for extra-mural research to be carried out by some other organization is appropriate to functional responsibility, although the management of such work when initiated is executive.

During the preparation of the budget submissions, the co-ordination of financial requirements can be made a functional responsibility, and thus the various schemes from the separate establishments can be dovetailed before consideration by the Research Board. This is a logical consequence of strategic planning.

Where the organization is large, strategic planning will embrace all aspects in all establishments or groups. Tactical planning applies only to the establishment, group or section the effort of which is under consideration, and is necessary to the efficient discharge of the executive responsibility of management.

INTERNATIONAL PROTECTION OF BIRDS

The sixth Conference of the European Continental Section of the International Committee for Bird Preservation was held in the village of Beetsterzwaag, Friesland, Holland, during June 3–7, under the chairmanship of Dr. Boje Benzon (Denmark). The meeting was attended by delegates of the national sections of Austria, Belgium, Denmark, France, Germany, Great Britain and Northern Ireland, Italy, Netherlands, Norway, Sweden and Switzerland, together with representatives of the International Union of Biological Sciences, the Conseil International de la Chasse and an observer from Luxembourg.

One of the most important achievements of the European Section was the drawing up of an International Convention for the protection of birds which was signed *ad referendum* by the representatives of twelve European powers in Paris in 1950. Switzerland was the first country to ratify it in 1954, and was followed by the Netherlands, Spain, Belgium and Iceland; but in spite of the new Bird Protection Act of 1954 on which great hopes were placed, the United Kingdom Government has still expressed inability to ratify. This Convention is a revision of the Paris Convention of 1902, which was confined to birds useful to agriculture only, and embraces the modern conception of bird protection—that as a main principle all birds should be protected—exceptions being made for species which are considered harmful, and for special circumstances and conditions. After a frank discussion, the general feeling of the meeting was expressed in a resolution pointing out that certain governments might be hesitant to ratify the Convention on account of minor differences, and directing attention to the 'escape clauses' provided.

In another international agreement, vitally affecting birds, the International Convention for the Prevention of the Pollution of the Sea by Oil, the United Kingdom, however, has taken the lead, for it was at the Inter-Governmental Conference convened in London in 1954 that this Convention was drawn up. The United Kingdom was the first country to ratify it, in 1955; the representatives of Denmark, the German Federal Republic and Sweden reported that their Governments had since taken this step, while others stated that their respective Governments were in the process of passing, or on the point of introducing, legislation to enable ratification. Thus after more than thirty-five years, during which thousands of sea-birds have perished annually, a concrete step forward to combat this evil has been made.

The diminution of the birds of prey all over Europe is causing concern, and it was unanimously agreed that these birds were in need of better protection and that to achieve this end education as to their value was urgently required. In this matter Great Britain, where full protection is accorded to all birds of prey except the sparrowhawk (*Accipiter nisus*), is outdistanced only by The Netherlands, where all birds of prey, without exception, are protected. This overall protection was recently given in Holland as a result of the frequent mistakes which had been made in shooting other species which are difficult to distinguish from the sparrowhawk.

Reports on the diminution of the white stork were given from several countries, though from Austria and Hungary came news of an increase in numbers. The causes of the diminution of this large white and black bird are varied; as with most species, more intensive cultivation being considered one of the prime reasons. It was stated that large numbers of storks meet their death by flying into overhead wires and tall chimneys, and France and Spain were blamed for the fact that though the stork is legally protected in those countries, the law is not enforced and large numbers are shot. It was alleged that in Spain hunters especially aim at killing ringed storks as they like to collect the rings as trophies, and in view of this it has been decided in the Netherlands to cease all ringing of young storks for the present. A French speaker stated that from his personal observations, white storks certainly did not appear to be diminishing in Central Africa, and put forward the suggestion that numbers of this species might possibly be losing their habit of northerly migration. In Holland and other countries suitable platforms have been erected to encourage storks to nest, and this scheme has already met with encouraging success; it would appear, however, that the birds are becoming lazy, as it has been observed that they prefer nests already prepared to a mere nesting platform.

The use of pesticides and their effect on wild life was dealt with at length by speakers from The Netherlands and Germany and supported by statements from Belgium, France, Great Britain, Sweden and Switzerland. The great difficulties of this problem were fully realized and it was agreed that in view of the time required fully to assess the effects of pesticides on wild life and the constantly changing situation with regard to the production of these substances, this subject should be kept permanently on the agenda of the Committee. In the meantime, a resolution was passed urging all Governments to take the necessary steps to prohibit the further use or sale of any pesticide which had been proved to be excessively destructive to birds and other forms of wild life.

Among other subjects discussed at the meeting were the control of the export and import of wild birds' eggs, birds which are a menace to other species, the protection of the skylark and the effect of shooting during severe frost. National representatives also reported on the establishment of new bird reserves, particularly on migration routes, and the state of bird preservation in their respective countries.

Throughout the meeting it was evident how difficult it is for one country to pass and maintain protective measures unless her neighbours do likewise, and that, to ensure the effective preservation of birds, international collaboration is imperative. But the cordial atmosphere which prevailed, and the obvious desire of all national representatives, without exception, to co-operate to the fullest extent, were striking features of the discussions.

Immediately before the Conference, a meeting of the Executive Board of the International Wildfowl Research Bureau (a branch of the International Committee for Bird Preservation) was held under the chairmanship of the honorary director, Dr. Edward Hindle, at which the problems of the conservation of wildfowl, the Anatidae in particular, were dealt with.

PHYLLIS BARCLAY-SMITH

INTERNATIONAL SCIENTIFIC RADIO UNION

AN account of the eleventh general assembly of the International Scientific Radio Union, held in The Hague during August 23–September 2, 1954, has already appeared in *Nature* (September 3, 1955, p. 451); and this, together with a later account (*Nature*, April 7, p. 652), dealt with three (Parts 1, 4 and 8) of the eight parts of Vol. 10, which forms the published proceedings of the assembly. The remaining five parts have now been published*.

Part 2 deals with the work of Commission II on "Radio and Troposphere". As the chairman's summary of the proceedings shows, this Commission is very active in research on the influence of meteorological conditions on the propagation of radio waves by normal refraction processes to distances well beyond the horizon, and by the phenomena of scattering to distances of several hundred kilometres.

"Ionospheric Radio", the title of Commission III, is covered in Part 3. During the general assembly, this Commission held six technical sessions which dealt with the behaviour of the ionosphere at high latitudes, the morphology of the *D*-layer, rocket investigations of the ionosphere, absorption and forward scattering by the ionosphere, and with geomagnetic distortion and storms in the *F*2-layer. Many of the resolutions of the Commission are concerned with the important and very active part to be played by the International Union in the programme for the forthcoming International Geophysical Year.

The proceedings of the deliberations by Commission V, "Radio-Astronomy", are described in Part 5. The work of this Commission has already resulted in the publication of three special reports (see *Nature*, December 10, 1955, p. 1110), and the whole subject is being actively pursued on a basis of international co-operation. Sub-commissions have been established to study continuous measurements of solar radio emission, and to explore the possibilities of standardizing equipment and measuring techniques. The importance of making adequate frequency allocations for radio astronomy is emphasized; and in the case of such frequency bands as those in which the neutral hydrogen line is located, there is a need for international agreement on such allocations.

Part 6 describes the work carried out at the general assembly by Commission VI on "Radio Waves and Circuits". The resolutions of this Commission show that its work ranges over a wide field, including information and its measurement, the spectra of random signals, band-widths and time-constants, and the applications of abstract algebra to new circuit arrangements for equipment and antenna systems.

The title of Commission VII is "Radioelectronics", and the report of the chairman given at the end of Part 7 shows that there has been much discussion as to the manner in which the Commission will fit into the general pattern of the International Union. During the meetings, discussions were held on the subjects of solid-state and gaseous electronics, valves for microwave optics and electronics, and on the generation of radiation by gaseous processes; the last being dealt with jointly with Commission V as a subject of mutual interest. A recommendation was made to form a joint commission between the International Scientific Radio Union and the International Union of Pure and Applied Physics to provide means for the discussion of topics in electronics which do not properly belong in the field of radio.

All the publications referred to above contain full details of the scientific sessions, all the national reports in full, together with, in most cases, carefully selected lists of references; the summarizing reports of the respective chairmen with the resolutions of the Commissions adopted at the general assembly are also included. The publication of these remaining parts completes the official record of The Hague meeting of the International Scientific Radio Union, 1954.

NATIONAL INSTITUTE OF AGRICULTURAL BOTANY, CAMBRIDGE

REPORT FOR 1956

AT the annual general meeting of the Fellows of the National Institute of Agricultural Botany, held in Cambridge on July 13, Prof. E. T. Jones, director of the Welsh Plant Breeding Station, received the Institute's Cereal Award for his work in breeding the new winter oat 'Powys'. This variety combines the best features of the well-known *S.* 147 and *S.* 172 and has shown outstanding merit in a series of trials. It will not, however, be available for general distribution this year.

The thirty-sixth annual report* presented at the meeting records continued expansion of the work of the Institute and plans for further building-extensions have been under active consideration. Some changes in the organization of cereal trials have been completed, which will reduce the time before a decision regarding recommendation can be made from four to three years. 'Preliminary' trials of new varieties are now grown at four of the thirteen regional centres, and with the aid of special plot combine-harvesters reliable results can be obtained in the first year. The more promising varieties go into 'main' trials, with larger plots at more centres, incorporating three levels of nitrogenous top dressing, in addition to a basic dressing to ensure adequate supplies of phosphorus and potassium. Another new feature is the trial of varieties used as 'controls' during the past thirty-five years, to see how far modern cereals are improvements on the older ones. The transfer of responsibility for the production of stock seed of all the Aberystwyth strains of grasses and clovers from the Welsh Plant Breeding Station to the Institute has necessitated much reorganization of technical work and contracting arrangements, and a special granary extension for these seeds is in course of erection. Progress continues with the plans for supervising the quality of seed stocks grown in Britain. Cereal crops entered for inspection again exceeded 100,000 acres, and nearly 54,000 acres were field-approved. A Comprehensive Certification Scheme for special cereal seed stocks was operated on a limited scale for the first time in 1955, and it is hoped that the arrangements for the National Comprehensive Certification Scheme for Herbage Seed will be complete in 1956.

The report also provides useful information regarding the performance of different varieties of potato, pulses, roots, fodder and oil crops, and field vegetables. Management trials carried out with lucerne showed that the best time for the first cut is the early bud stage. This both gave the best-quality hay, and, as a result of the earlier second growth, enabled four cuts to be taken each season. For those interested in grasses, the classification of some seventy strains of perennial rye grass according to their time of flowering, and the results of trials with hormone weed-killers on grass seed crops are of particular value, relatively safe times for spraying being given for the different Aberystwyth strains.

Details of the work of the Official Seed Testing Station are included in the report. The large increase in cereal samples received for testing and the high percentage with germination which fell below the authorized minimum standard reflect the bad harvesting conditions in 1954.

STUDIES IN MUTAGENESIS

Production of Bacteriophage Mutants by a Disturbance of Deoxyribonucleic Acid Metabolism

IN experiments in which the pyrimidine derivative 5-bromouracil was incorporated into the deoxyribonucleic acid of $T2r^+$ bacteriophage, according to the method of Dunn and Smith[1], it was observed that a large number of a variety of plaque-type mutants appeared among the progeny phages, as illustrated in Fig. 1. The observation of this apparently powerful mutagenic effect of 5-bromouracil led us to an investigation of the conditions upon which the production of phage mutant depends.

In a typical experiment, a culture of *Escherichia coli*, strain *B*, was grown with aeration at 37° C. in complete medium supplemented with 50 μgm./ml. 5-bromouracil, for four generations to a density of 2×10^8 cells/ml. (Complete medium is a glucose-salts medium[2] supplemented with 1 mgm./ml. sulphanilamide, 1 mgm./ml. vitamin-free casein hydrolysate, 25 μgm./ml. xanthine, and uracil equal to 5 per cent of any 5-bromouracil added. We had found that when commercial 5-bromouracil, which contained a 5 per cent uracil contamination, was added to complete medium, no further pyrimidines were necessary for bacterial growth. In complete medium plus pure 5-bromouracil, however, the bacteria required uracil for growth.) The bacteria were then centrifuged and resuspended in the same volume of complete medium plus various concentrations of 5-bromouracil, infected with 3×10^8 $T2r_2$ phages per ml., and the infection was allowed to proceed for 3 hr. At this time the bacteria were centrifuged, and the supernatant fluids were diluted and plated on broth agar. The results are presented in Fig. 2, where the 'infective yield' (the ratio of the number of infective, that is, plaque-forming, progeny to the number of input phage) is plotted as a function of the 5-bromouracil concentration in the medium. The percentage mutants (100 times the ratio of all mutant plaques to the total number of progeny plaques) is seen to be maximal at the concentration of 5-bromouracil giving minimal infective yield. No mutants were produced in the absence of 5-bromouracil. The quantitative results were observed to vary somewhat, depending on the exact growth conditions employed.

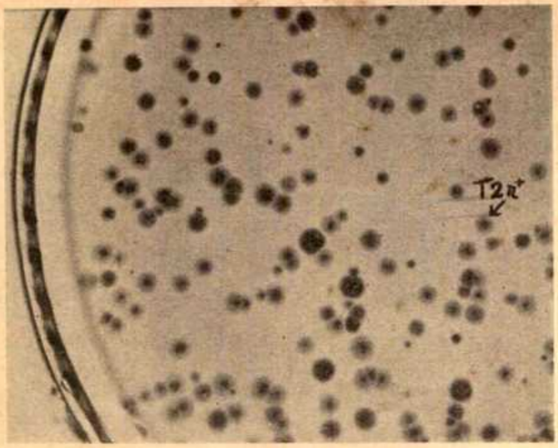

Fig. 1. Infective progeny of $T2r^{+}$ resulting from growth in complete medium plus 5-bromouracil

We have also studied the effects of other uracil derivatives and have found that 5-chlorouracil and 5-iodouracil, both of which are incorporated into phage deoxyribonucleic acid[1], gave yield and mutation patterns similar to those of 5-bromouracil, but that neither 5-aminouracil nor uracil itself produced mutants. In the absence of sulphanilamide, none of the three halogenated uracil derivatives had any mutagenic effect. Only plaque-type mutants have so far been investigated, but these have at times represented as high as 15 per cent of the total infective progeny. A large number of these mutants have been picked and replated three or more times on broth agar, and in almost all cases they kept their mutant identity. These mutants must, therefore, be stable and do not need 5-bromouracil to reproduce.

The appearance of mutants during growth in the presence of 5-bromouracil and sulphanilamide could be attributed either to a mutagenic action or to a selective enrichment of the mutants already present in the original stock at a frequency of 10^{-3}. The latter possibility was eliminated by the following two experiments. First, a one-step growth experiment[3] was performed. *E. coli* B was grown in complete medium plus 5-bromouracil as previously described and then infected in the same medium with one $T2r_2$ phage for every ten bacteria. After phage adsorption, but before lysis, the infection mixture was diluted into first and second growth-tubes containing 10^3 and 10 original phages per ml., respectively, and aliquots from each of the two tubes were plated at intervals before and after lysis. We found that mutant production was optimal when the phages were grown in the presence of at least 10^8 cells/ml. In order to simulate mass culture conditions in this experiment, the dilutions were made into a spent medium, that is, complete medium plus 50 μgm./ml. 5-bromouracil in which *E. coli* B had grown for 3 hr. and from which the bacteria had been afterwards removed by filtration. After lysis we found that while the total number of phages had increased some eighteenfold, the number of mutant phages had increased five hundredfold. To explain this result as due to selection, one would have to postulate a burst of five hundred for each pre-existing mutant. In this medium, however, the mutants were shown to have bursts of the same magnitude as the original stock. The second type of experiment was a single-cell burst experiment[4]. *E. coli* B was again grown as previously described, but this time infected with more than one $T2r_2$ phage per bacterium. After a few minutes, the unadsorbed phages were inactivated by dilution into $T2$ antiserum, and the infected bacteria were further diluted down to a level of about 10 cells/ml. Single drops of this dilution were distributed into each of sixty-six tubes, and after allowing ample time for lysis to occur, each tube was plated separately.

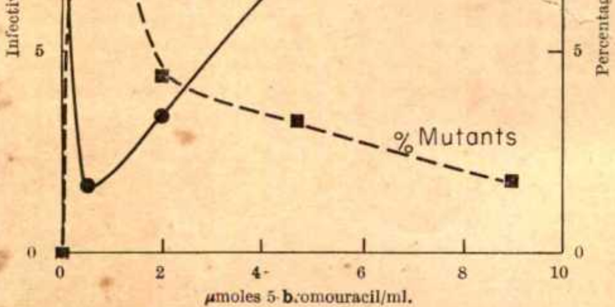

Fig. 2. Pattern of action of complete medium plus 5-bromouracil on phage production and mutation

In this experiment mass culture conditions were maintained by making the dilutions into a culture of 10^8 cells/ml. of uninfected $T2$-resistant *E. coli*, strain *B*/2 growing in complete medium plus 5-bromouracil. The results are given in Table 1. Any pre-existing mutant should have developed into a clone of mutant progeny. This was not observed; rather, of the thirteen plates containing mutant plaques, twelve had one mutant per plate and one had two mutants. The quantity A is calculated from the number of bacteria originally infected with phage. B is obtained from the Poisson formula, $P(O) = e^{-n}$, where $P(O)$ is the proportion of plates containing no plaques, and n is the number of infected bacteria per plate. The ratio of B to A, the fraction of the infected bacteria which released phage, is equal to 1, and therefore every infected bacterium produced infective phage. C is calculated from the number of plates which contain no mutant plaques, again using the Poisson formula. The ratio of C to B is the fraction of infected bacteria which released mutant phage. Since in the original infection mixture only one out of every 10^3 bacteria was infected with a mutant phage, the mutants appearing after lysis from 1 in every 4 bacteria must have arisen through mutation and not selection.

Table 1. SINGLE-CELL BURST EXPERIMENT

No. of plates	No. of plaques/plate	No. plates with mutants
28	0	—
11	1–5	2
13	6–9	4*
9	10–21	4
5	22–85	3
A, infected cells/plate (calculated from input)		0·75
B, infected cells/plate (calculated from Poisson law)		0·86
Ratio of *B* to *A*		1·1
C, infected cells/plate yielding mutants (calculated from Poisson law)		0·22
Ratio of *C* to *B*		0·26

* One plate contained 2 mutants

The mutagenic effect of 5-bromouracil in the presence of sulphanilamide must certainly be connected with a disturbance of deoxyribonucleic acid metabolism or structure. Another instance, in a different system, of mutagenesis resulting from an interference with deoxyribonucleic acid metabolism, more specifically thymine metabolism, is presented in the following communication by Coughlin and Adelberg. The most obvious proposal to explain the mutagenic action of 5-bromouracil is that the incorporation of this base into deoxyribonucleic acid may be directly responsible for the appearance of phage mutants. Both Dunn and Smith[1] and we have found that a large proportion of phages (total phages being estimated from optical density at 260 mμ) containing 5-bromouracil are non-infectious. The amount of thymine replaced by 5-bromouracil seemed to depend on the 5-bromouracil concentration in the medium. We have obtained a phage preparation the thymine of which was completely replaced by 5-bromouracil, but 9 per cent of the total phages still formed plaques of normal and mutant type. As yet, however, no correlation can be made between the amount of thymine replaced by 5-bromouracil and the percentage of mutants among the surviving infective progeny.

Sulphanilamide is known to inhibit methyl transfer by interfering with folic acid formation, consequently reducing the ability of the bacteria to synthesize thymine. But the combination of 5-bromouracil and sulphanilamide has further metabolic effects, not yet clearly defined, on reactions required for pyrimidine biosynthesis. Aside from its incorporation into deoxyribonucleic acid, 5-bromouracil inhibits thymine utilization, is reversed by thymidine competitively, and inhibits uracil formation or utilization.

While at present no definitive mechanism for the mode of action of 5-bromouracil and sulphanilamide can be proposed, it is hoped that further investigations of the biochemical aspects of this system may lead us to a better understanding of the biochemical nature of mutagenesis.

We are grateful to Drs. G. S. Stent, J. D. Smith, E. A. Adelberg, and W. M. Stanley for valuable discussions and suggestions, and to Mr. J. Toby for taking the photograph.

This work was aided by grants from the Lederle Laboratories and the Rockefeller Foundation.

Bacterial Mutation induced by Thymine Starvation

THE phenomenon of 'thymineless death' of *Escherichia coli* strain 15T^-, a thymine-requiring mutant, was discovered by Cohen and Barner[1]. Their experiments demonstrated that these bacteria lose their ability to give rise to colonies following incubation in a thymine-free synthetic medium which supports rapid growth of the prototrophic parent strain *E. coli* 15.

The purpose of this report is to present experiments which indicate that thymine starvation of these organisms has a mutagenic effect on the surviving cells. The effect of thymine starvation on the appearance of new mutants has been studied in the following manner.

The parent strain employed, *E. coli* 15 $T^-H^-N^s$, requires both thymine and histidine for growth and is unable to grow in the presence of 100 μgm. of *nor*leucine per ml. This strain was kindly supplied by Miss Hazel Barner, who isolated it following ultra-violet irradiation of *E. coli* 15T^-. The mutational event chosen for the study of mutagenesis was the one which conferred independence of histidine on the parent strain. An exponentially growing culture was placed under conditions of thymine starvation by washing it twice with distilled water and resuspending it in a 'basic mineral medium'[2] containing 2 mgm. of glucose and 10 μgm. of histidine per ml. At various times, aliquots were withdrawn from the thymine-free medium, chilled and divided into two samples. One sample was plated on broth agar for determinations of viable cell counts. The other sample was washed twice in distilled water and concentrated by centrifugation, then shaken for twenty minutes to free the suspension from clumps of cells. Aliquots of 0·1 ml. of the concentrated cell suspension containing about 1 × 10⁸ cells/ml. were then spread on the surface of agar plates of 'basic mineral medium' containing 2 mgm. of glucose and 2 μgm. of thymine per ml. of washed agar. Colony counts of the presumptive histidine-independent mutants were made after incubation at 37° C. for five days, and random colonies were picked and tested to verify their thymine-dependent and histidine-independent conditions.

The ability of this procedure to recover histidine-independent (H^+) mutants was checked in the following manner. A suspension was prepared containing a known number of H^+ cells, and aliquots of this suspension were mixed with suspensions of histidine-dependent (H^-) cells in various ratios approximating actual experimental conditions. The individual suspensions and the mixtures were washed, concentrated and plated as described above; the results indicated that these procedures afford quantitative recoveries of mutant cells present in predominantly wild-type populations.

The results of a typical experiment are presented in Table 1, where it can be seen that a hundred-fold proportional increase of H^+ mutants appeared among the survivors of 185 min. of thymine starvation. This can be compared with the results of an ultra-violet irradiation of the same parent strain, which yielded a two-fold proportional increase of H^+ mutants among the survivors of a dose killing 98·6 per cent of the cells.

The results in Table 1, however, can be taken as only presumptive evidence of a mutagenic effect of

Table 1. PROPORTIONAL INCREASE IN H^+ MUTANTS DURING THYMINE STARVATION

5·8 × 10^7 cells, genotype $T^-H^-N^s$, suspended in thymine-free synthetic medium at time zero. Conditions as described in text

Minutes thymine starvation	Per cent killed	H^+ mutants per 10^8 viable cells	H^+ mutants per ml.
0	0	22	13
80	56	42	10
140	87	101	8
185	99	2,540	10

thymine starvation, since the absolute number of viable mutants per ml. of suspension did not increase. This could mean that thymine starvation exerted only a selective effect: that is, the H^+ mutants initially present in the untreated population could have survived thymine starvation better than the population at large.

An experiment was therefore performed in which a pure culture of T^-H^+ cells was subjected to thymine starvation. The H^+ cells were found to 'die' at a rate comparable to the rate of 'thymineless death' of H^- bacteria. Nevertheless, the possibility still remained that H^+ cells might behave differently in a suspension of mixed H^+ and H^- cells, where interactions between the two cell types might significantly alter the survival of H^+ organisms. Consequently, a more direct experiment was designed to test the survival of the H^+ cells under conditions simulating those of the actual mutagenesis experiment. For this purpose a small number of H^+ cells was mixed at zero time with a suspension of H^- organisms. The two cell types were distinguished by the presence of genetic markers for *nor*leucine sensitivity (N^s) and *nor*leucine resistance (N^r), respectively. The $T^-H^-N^r$ strain was obtained by plating a washed exponential phase culture of $T^-H^-N^s$ cells directly on synthetic growth medium containing 100 μgm./ml. of *nor*leucine, while the $T^-H^+N^s$ strain was obtained by plating the survivors of 185 min. of thymine starvation on synthetic medium lacking histidine.

The proportion of spontaneous *nor*leucine-resistant mutants in the original suspension of $T^-H^+N^s$ cells was 103 per 10^8 viable cells. However, only 220 cells of the latter type were added per ml. of mixed suspension at the beginning of the experiment, so that the presence of any significant numbers of $T^-H^+N^r$ cells among them was deemed highly unlikely.

A summary of the results of this experiment is presented in Table 2. The surviving numbers of added $T^-H^+N^s$ organisms per ml. of original suspension at any given time during thymine starvation was calculated by subtracting the number of colonies formed on agar containing glucose, thymine and *nor*leucine, from the number of colonies arising on similar medium devoid of *nor*leucine. The validity of this method was verified by picking a random sample of H^+ mutants from the *nor*leucine and minimal plates and testing them for sensitivity to *nor*leucine as well as for histidine independence and thymine dependence. From the data presented in Table 2 it can be seen that all the $T^-H^+N^s$ cells added at the beginning of the experiment were eliminated from the population after 225 min. of thymine starvation, establishing that a selective mechanism favouring the preferential survival of histidine-independent cells is not operative during our experimental conditions. Hence the substantial increase in the proportion of $T^-H^+N^r$ mutants can best be explained as resulting from an induction of new mutants.

Table 2. THYMINE STARVATION OF $T^-H^+N^s$ CELLS IN MIXED SUSPENSION WITH $T^-H^-N^r$ CELLS

Cells of type $T^-H^-N^r$ mixed with cells of type $T^-H^+N^s$ at time zero to give final cell densities of 6·2 × 10^7 and 220 per ml., respectively. Details in text

Per cent H^-N^r cells killed	H^+N^r mutants per ml.	H^+N^r mutants per 10^8 viable cells	H^+N^s mutants per ml.
0	53	86	220
13	7	14	—
50	20	65	82
76	50	345	1
92	59	1,162	0

It may also be noted in Table 2 that while the $T^-H^-N^r$ cells undergo a 13 per cent reduction in viable cell count due to thymine starvation, the $T^-H^+N^r$ cells are reduced from 53 per ml. to 7 per ml.: a reduction of 87 per cent. This disproportionate death of H^+ mutants which have arisen spontaneously in a growing culture of H^- cells has been observed repeatedly in the early stages of thymineless death, and is probably a consequence of the multinucleate condition of the bacteria and the dominant nature of the H^+ condition[3]. If the loss of viability due to thymine starvation is the result of random nuclear inactivation, as indicated by the work of Fuerst and Stent[4], then a bacterium would die only after all its nuclei had been inactivated. An H^+ mutant, on the other hand, would effectively disappear from the population following inactivation of only those nuclei specifically carrying the H^+ mutant character. If a significant proportion of the H^+N^r bacteria were heterokaryotic with respect to the H^+ genotype, bacterial cell 'death' would not be equivalent to mutant or nuclear 'death'. Hence in the initial stages of 'thymineless death', where the majority of the bacteria are presumably in a multinucleate condition, the mutant (H^+) count would decrease at a faster rate than the viable count.

It should be noted that in the reported experiments no provision was made for the delayed expression of mutation, since the washed cells were plated directly on media devoid of histidine. Indeed, the results of one experiment in which the survivors were plated on limiting amounts of histidine showed that only a fraction of all the induced mutants is recovered with our standard procedure. The true number of induced mutants is, therefore, greater than that indicated by the figures in the tables.

Any explanation of the causative mechanism for the reported mutagenesis would be strictly speculative at present. It is of interest, however, that Dunn and Smith[5] have reported an increased appearance of the base 6-methylaminopurine in the deoxyribonucleic acid of strain 15T^- under conditions of limiting thymine, and the relation of the metabolism of this base to the mutagenic activity of thymineless death is now under investigation.

The experiments of Litman and Pardee (see previous communication) have indicated a correlation between appearance of coliphage mutants and interference with deoxyribonucleic acid metabolism. From our experiments it might also be inferred that bacterial mutation can be a consequence of disrupted deoxyribonucleic acid metabolism. For the moment, however, we can conclude only that the state of specific thymine starvation is mutagenic in *E. coli* for the one phenotypic property studied.

The Sun's General Magnetic Field

SOME of the recent theoretical discussions of the magnetic field of the Sun have tended to throw the subject into a state of confusion[1–3]. In particular, H. Alfvén[3] asserts that ". . . it is at present impossible to derive a value of the sun's general magnetic field from spectroscopic measurements", and that "quite without justification it is assumed that Zeeman-effect measurements give an accurate value of the solar magnetic field".

Such a statement is in conflict with the published observations of weak solar magnetic fields, and of the discussion that has been given to these observations[4]

Alfvén begins with the not unreasonable assumption that in the turbulent photosphere there is equipartition of energy between the kinetic and the magnetic modes. He argues that the intensity of the spectral line in which the Zeeman effect is measured s a function, f, of density, ρ, and temperature, T, and that in the granules ρ, T and the magnetic field H are coupled, so that "it is not at all likely that the average Zeeman effect gives an average of the magnetic field". Alfvén assumes (apparently on the basis of a particular theory of the origin of sunspots) that there is a general field H_0 of the order of 10 gauss. This is superimposed on the turbulent field H_t, so that in some parts of a granule the resulting field is $H_0 + H_t = + 10 + 300 = + 310$ gauss, whereas in other parts of it the field is $H_0 - H_t = + 10 - 300 = - 290$ gauss. The average then depends on the function f (ρ, T) and the way in which ρ and T are coupled with H. If f is systematically smaller for positive values of H_t than for negative values, 'the measured H_m may very well be negative even f the real field H is positive, and its absolute value may differ by orders of magnitude". Hence, accordng to Alfvén, "no conclusion can be drawn about the general magnetic field from the Zeeman-effect measurements and the results of these measurements are not relevant".

I believe that Alfvén greatly over-estimates the mportance of the possible coupling of H with line ntensity, and that his conclusion may readily be refuted by consideration of the published observaions.

According to Alfvén's argument, the systematic effect of f and the way in which ρ and T are coupled with H should provide a large bias (probably subject to a centre-to-limb effect) underlying the much maller true field. But the measurements of the Zeeman effect are absolute, and they show no trace f bias. Vast areas of the Sun, and occasionally, near sunspot minimum, the greater part of the solar disk, how no observable field distinguishable from zero. The limit is about 0·5 gauss for the 'noise' peaks, nd much lower for any possible bias.

A further very significant result that was brought ut in the discussion of the extensive series of observaions with the solar magnetograph concerns the measred magnetic fields of bipolar magnetic (BM) regions, which exhibit a vast range of total magnetic flux. The large bipolar magnetic regions, while young, characteristically contain leading and following sunspots of opposite polarity. For such spots, G. E. Hale[5] established the well-known laws of magnetic polarity that pertain to the N- and S-solar hemispheres and to the alternation in successive 11-year sunspot cycles. As we have indicated, well-defined bipolar magnetic regions have approximate equality of positive and negative flux in the respective parts; the observations substantiate the concept of a localized loop of a submerged toroidal field rising above the surface, as suggested by Cowling[6]. Now in the N- or S-hemisphere of the Sun, in a given sunspot cycle, the same relative polarity of leading and following parts of all well-defined bipolar magnetic regions is exhibited over the whole range of magnetic intensity, from the very strong, spotted bipolar magnetic regions ($H \approx 3{,}000$ gauss) down to those (unspotted) of minimal size having average field intensities of only one or two gauss. Furthermore, weak bipolar and unipolar magnetic (UM) regions are frequently identifiable and measurable for days or weeks as they are carried across the disk by the solar rotation, even though they may be surrounded by vast areas having no outstanding field.

This disposes completely of the idea that the turbulent field of the granules systematically reverses, or appreciably biases, the measured Zeeman effects of weak magnetic regions on the Sun.

If, then, the polarity and approximate magnetic intensity of weak bipolar magnetic regions can be reliably observed, there is no reason for doubting the observations of weak fields, consistently positive near the north pole, negative near the south pole, that constitute the 'general' magnetic field of the Sun. After correction for darkening at the limb and for the presumed projection factor, the average intensity of the general field near the poles has been stated to be of the order of one gauss[4]. This is an order of magnitude weaker than the field required by Alfvén's theory of sunspots, and as Alfvén states, his solar model "seems to be in striking conflict with the Zeeman-effect measurements if these are interpreted in the naive way as really measuring an average field". Since there is as yet no generally accepted theory of the magneto-hydrodynamic effects in solar granules, and since it would appear that such a theory, when finally perfected, will probably lead to rather minor refinements of the measured field intensities when averaged over large regions, we may have to continue with the present interpretation of the observations.

It may be mentioned that a second solar magnetograph[7], incorporating certain technical improvements and operating with the advantage of the better sky of Mount Wilson as compared to Pasadena, confirms the existence and polarity of the weak polar fields of the Sun previously reported.

Determination of Changes in the Dimensions of the Earth from Palæogeographical Data

Essentially, there are two opinions concerning the volume of the Earth: (1) its volume is decreasing, that is, the Earth is shrinking; (2) its volume has remained practically constant during geological times.

Geological observations have clearly established that the volume of the hydrosphere has grown throughout the geological past; the increase, however, has not been more than about 4 per cent of the whole volume since early Cambrian times.

In the case of a shrinking Earth, the average depth of the oceans must have increased. As a consequence of the higher sea-level, the area of the continents covered by sea water should be increasing.

If the volume of the Earth has remained constant, the amount of water-covered areas is influenced only by crustal movements and, on average, it should oscillate about a constant value.

The problem of the constancy or otherwise of the volume of the Earth can be solved, therefore, on the basis of palæogeographical data. We have only to establish the amount of the areas covered by sea water in different geological ages: a definite increase in the average values means a shrinking Earth, whereas their constancy indicates that on balance the volume of the Earth has not appreciably changed.

Fig. 1 represents the water-covered continental areas computed from the palæogeographical maps of T. M. Strahow; Fig. 2 is a similar diagram compiled from thirty-four palæogeographical maps recorded by H. Termier and G. Termier.

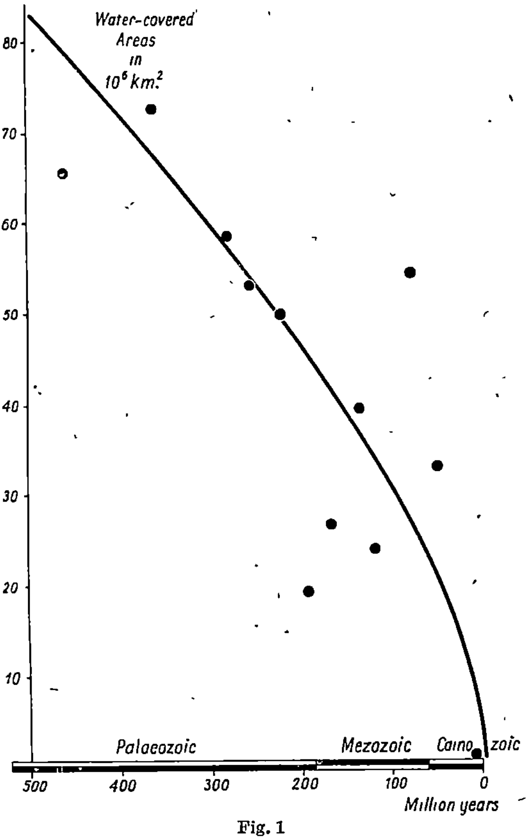

Fig. 1

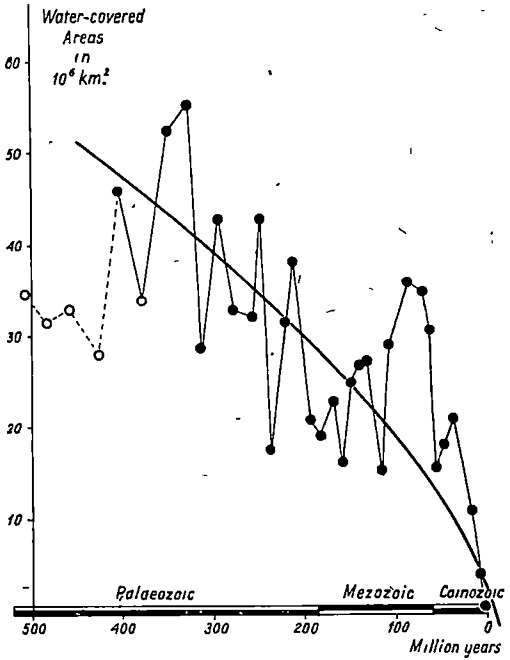

Fig 2

In both diagrams the data plotted show a definite decrease in the course of the geological ages, indicating that there has been a cumulative increase of the radius of the Earth. Indeed, palæogeographical data provide evidence for the hypothesis that the Earth has expanded.

Figs. 1 and 2 can be used for giving the average rate of increase of the radius of the Earth, assuming that, on average, the hypsographic character of the Earth has remained the same since early Palæozoic times. Fig. 1 yields a radius increase of 0·66 mm./year; Fig. 2, compiled from the Termiers' data, gives 0·4 mm./year.

It is concluded that the annual increase of radius, according to palæogeographical data, has averaged about 0·5 mm./year during the past 500 million years.

Magnetic Perturbation of the Lowest Triplet States of Aromatic Molecules by Dissolved Oxygen

The absorption spectrum of benzene in the region 2795–3650 A. has been measured by Miss Pitts[1]. She observed a shoulder at approximately 2900 A. which has been tentatively assigned by Pariser[2] as a transition to a ${}^3E_{1u}$ state. Since it had been shown that oxygen dissolved in benzene absorbs strongly in this region[3], the spectrum has been re-investigated using pure benzene saturated with air or with nitrogen A Beckman Model *DU* spectrophotometer with 5-cm. silica cells was used, and the results obtained are shown in Fig. 1. No shoulder around 2900 A. can be detected, although in most other respects the curve for air-saturated benzene is in reasonably good agreement with that of Miss Pitts. The absorption

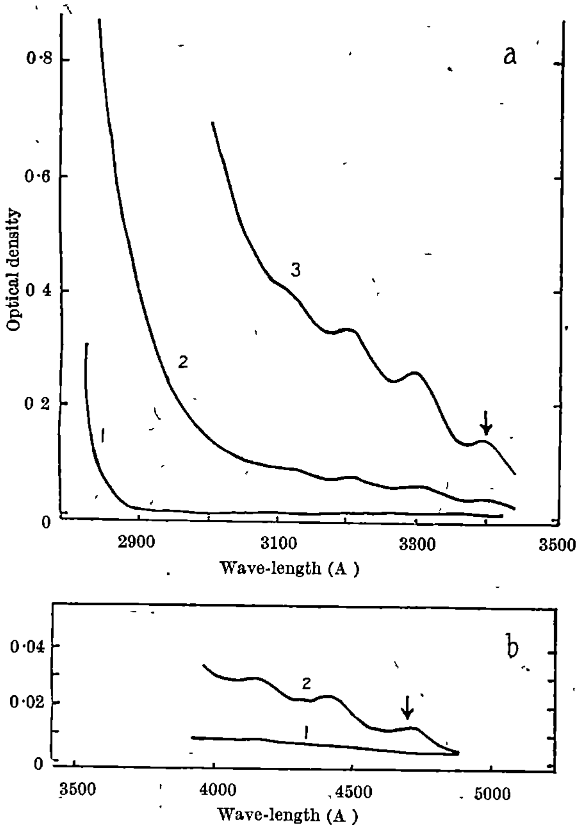

Fig. 1. (*a*) Absorption of liquid benzene saturated with (1) nitrogen; (2) air; (3) oxygen. (Blank—'Spectroscopic' methyl cyclohexane.)
(*b*) Absorption of naphthalene (2·8 *M* in ethylene dichloride) saturated with (1) nitrogen; (2) oxygen; and measured in a 5-cm. cell (Blank: A solution of methyl cyclohexane in ethylene dichloride.)
All measurements at approximately 22° C. Arrows indicate the position of the shortest wave-length phosphorescence bands (ref. 4)

spectrum of the pure compound at room temperature therefore seems to provide no evidence for a triplet-level of benzene at about 34,000 cm.$^{-1}$.

A striking effect was, however, observed at longer wave-lengths. The well-established[1,4] 'triplet'-bands around 3300 A. disappeared when the dissolved atmospheric oxygen was replaced by nitrogen. Conversely, they appeared much more strongly in benzene saturated with pure oxygen (see Fig. 1*a*). There is little doubt that these bands are in fact due to a transition to a triplet state (probably ${}^3B_{1u}$[2]). Thus they show the usual approximate 'mirror image' relationship with the phosphorescence bands[4]. (The absorption band at 3507 A. reported by Miss Pitts had not been observed previously, and was not found in the present work, even when 10-cm. cells were used.) The effect of the dissolved oxygen may accordingly be attributed to spin-orbit perturbation of the triplet-level by the inhomogeneous field of the paramagnetic oxygen molecule. (Oxygen dissolved in benzene has its normal paramagnetic susceptibility[5].) That magnetic perturbation of higher singlet–triplet transitions might be responsible for the principal absorption shown by oxygen dissolved in aromatic solvents was originally considered by Kasha (personal communication). A magnetic perturbation of a singlet–triplet transition has previously been observed in emission by Yuster and Weissman[6], who found that the phosphorescence life-time of the gadolinium complex of dibenzoyl methane was about 1/50 of that expected from the life-times of the lanthanum and lutetium complexes. Since a saturated solution of oxygen in benzene is approximately 11 *M* with respect to benzene, and only 0·008 *M* with respect to oxygen, the perturbing effect of the oxygen molecule is very much greater than that of the gadolinium ion, in spite of its smaller magnetic moment. Weak (possibly collisional type) complex formation probably takes place between benzene and oxygen, but it is unlikely that this alone will appreciably increase the singlet–triplet probability.

It is clear that the unperturbed singlet–triplet bands of benzene must be considerably weaker than has been previously supposed. This is supported by the long phosphorescence life-time of the benzene triplet[4].

Similar effects have also been observed for naphthalene, where the singlet–triplet bands in absorption were located for the first time (Fig. 1*b*). Magnetic perturbation by oxygen (possibly under pressure) may therefore, in certain cases, be a useful alternative to the heavy-atom technique[4] for detecting and confirming triplet-levels of aromatic molecules. The triplet-level of bromobenzene is already considerably perturbed by the heavy bromine atom, and very little change in the well-defined triplet absorption band was observed on saturation with oxygen.

Finally, it may be noted that the above results support the suggestion[7] that the quenching effect of oxygen (and nitric oxide) on the fluorescence of aromatic hydrocarbons is due to a magnetic perturbation which facilitates the excited singlet–triplet radiationless transition.

I wish to thank the University of Oxford for an I.C.I. Research Fellowship.

Pitch of Inharmonic Signals

IT is well established that a sound consisting of adjacent harmonics is perceived as having the pitch of the fundamental frequency. This pitch is to be attributed to a component of subjective perception, that is, the combined impression of some or all of the tones presented. Such a component, which is not susceptible to further aural resolution, is called a residue[1].

This phenomenon has been studied by the use of an amplitude-modulation method which permits the production of inharmonic signals as well. A pure-tone carrier A_x is modulated by a signal consisting of N components with frequencies B_x, $2B_x$, etc. The modulator produces a signal containing the carrier and the upper and lower side-bands. The components are equidistant but not necessarily harmonic.

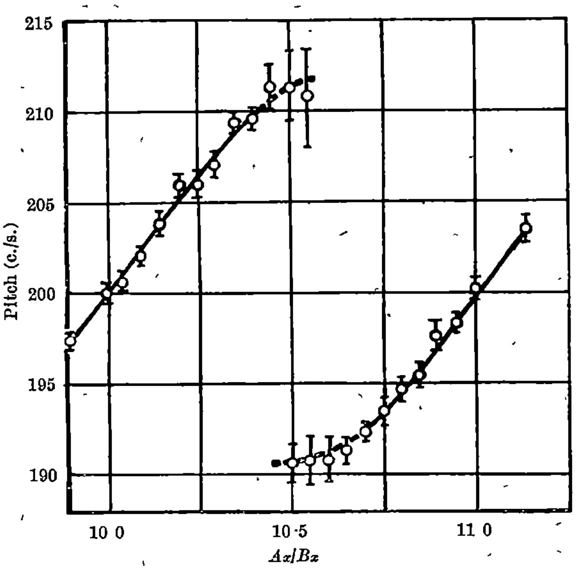

Fig. 1. Pitch versus carrier frequency. Modulation frequency 200 c./s.

It is observed that such 'coherent' inharmonic signals sound as stable and smooth as harmonic signals. The pitch has been determined by alternating the signal (X) with a harmonic signal (S) of adjustable fundamental frequency. The comparison signal (S) is produced by the same method as (X), the modulation frequency B_S being synchronized by the carrier A_S. The listener is then asked to vary the frequency A_S (which causes a corresponding variation of B_S) until the sounds (X) and (S) have the same pitch. The pitch-level of (X) is then the frequency B_S.

A typical result showing the dependence of pitch on the carrier frequency is shown in Fig. 1. In this experiment B_x has been kept constant. From Fig. 1 it will be noticed that the pitch increases with increasing carrier frequency. The relative variations of pitch in the neighbourhood of a harmonic situation are slightly larger than the relative variations of the carrier frequency. Midway between two harmonic situations, the pitch is indeterminate. The point exactly half-way is characterized by the component frequencies being odd multiples of half the modulation frequency. Careful listening reveals no trace of a pitch corresponding to $\frac{1}{2}B_x$, notwithstanding the low tonality of the sound.

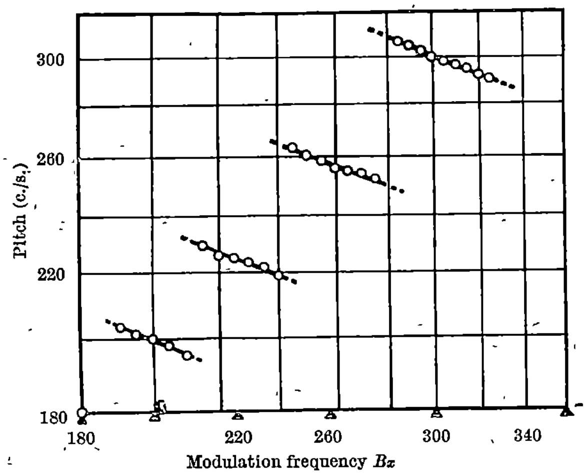

Fig. 2. Pitch versus modulation frequency. Carrier frequency 1,800 c./s.

When the pitch in the neighbourhood of a harmonic situation is exactly proportional to the carrier frequency, the pitch should be independent of the modulation frequency. The deviations from proportionality were therefore isolated in a second experiment in which the modulation frequency is varied. Fig. 2 shows a typical result of an experiment with constant carrier. Around a harmonic situation, the pitch drops with increasing modulation frequency B_x. The graph is again composed of several branches that are centred around harmonic situations and separated by regions of doubt.

A coherent inharmonic signal repeats itself over a much longer time than the period of the modulation signal. In the experiments, no beats due to the inharmonicity are observed, as long as the components of the stimulus are perfectly equidistant. This means that, when the envelope of the wave-form is constant, the tone quality of the residue is not affected by variation of phase or frequency of the fast oscillations within the envelope (which are determined by the carrier). In experiments that involve a change of the envelope, for example, by using an incoherent modulation signal, the residue quality is found to be affected[2].

It seems that the tone quality of the residue is greatly determined by the envelope of the signal, and the pitch by the 'fine-structure'. This simplified separation of phase and pitch effects is manifest in nearly all cases, except when the signal approaches the frequency-modulation condition[3].

Cleavage Fracture of Bismuth Single Crystals

EARLIER work[1] on the tensile stress necessary to cause cleavage fracture in zinc single crystals has shown that Sohncke's law was not obeyed. (Sohncke's law states that a crystal will break when the stress normal to the cleavage plane reaches some critical value). However, it is clear from the literature[2] that for some metal single crystals, notably bismuth, antimony and tellurium, Sohncke's law is obeyed. A study of the cleavage fracture of bismuth crystals was therefore undertaken in an attempt to discover the underlying cause of the difference of behaviour of zinc and bismuth.

The bismuth used contained 0·008 per cent lead; 0·0046 per cent tin; 0·0040 per cent iron; 0·0024 per cent antimony; 0·0018 per cent arsenic; 0·0015 per cent copper; 0·0015 per cent sulphur. It proved impossible to extract single crystals grown in precision-bore tubes without causing mechanical twins, and a technique for growing single crystals from a metal rod was developed from a method described by Noggle[3]. A moist mixture of alumina with an alumina clay bond was rammed around a poly-

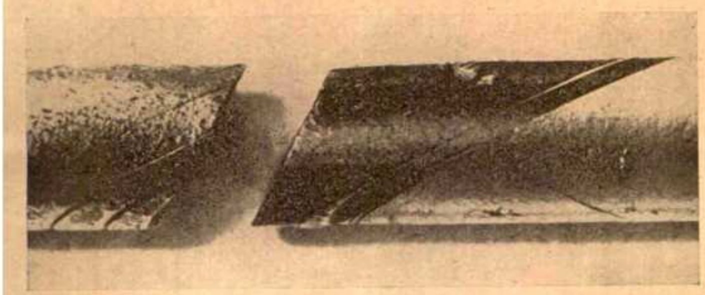

Fig. 1. Fractured bismuth crystal, illustrating crystallographic difference between cleavage and composition planes. × 3

crystalline rod to form the mould and, after drying, the single crystal was then grown. The mould material powdered very easily and the single crystal could be extracted without damage. The crystals used were about 7 mm. in diameter and at least 60 mm. long.

The crystals were orientated by the Laue back-reflexion method. The rhombohedral lattice of bismuth is very nearly face-centred cubic, and high accuracy of angular measurements is necessary to distinguish a (111) plane with certainty from a $(11\bar{1})$. (Both types of planes are possible cleavage planes.) The necessary angles and method used are to be published elsewhere. As yet, it has not proved possible to grow crystals of all orientations, and tensile tests have so far only been carried out on crystals with χ_{111} (the angle between the (111) plane and the longitudinal axis of the crystal) between 0° and 35°. Before the tensile test, all crystals were first etched and examined carefully for any signs of twins; generally none was visible. They were then electro-polished. The tensile tests were carried out at room temperature, the load being applied as axially as possible. In two of the crystals there were signs of twins developing as the load was increased to fracture; the behaviour of the other crystals gave no cause for suspecting the development of twins during the increase of load. But all crystals were etched after fracture so that the position of any twins could be observed.

This etch revealed a totally unexpected feature which apparently has not been noted in the earlier work on bismuth single crystals. The cleavage fracture did not, as in zinc, separate two parts of the specimen with the same lattice orientation, but was a plane separating a large twin from the original matrix. Fig. 1 shows clearly that on one side of the fracture there is a large twin extending completely across the crystal diameter. The other side of the fracture is almost entirely the original matrix, although there are one or two small twin lamellæ.

The crystallographic nature of the planes of the cleavage has been established as the $(11\bar{1})$ plane in the matrix and (111) plane in the twin. This is not the same as the normal composition plane of the twin and matrix, the (110). The difference between the two planes is obvious in Fig. 1. Thus, while the phenomenon resembles the 'parting' phenomenon in calcite[4], there is a difference in that the latter occurs at the twin/matrix composition plane. Zappfe[5] has seen the development of cracks between twins and matrix in bismuth–antimony alloys, which he describes as 'parting' on the twin matrix composition plane. But since he was working on polycrystalline material, crystallographic identification was difficult and the phenomenon may have been the same as that described here. Cahn[6] has found evidence of the existence of 'parting' in uranium; but he also could not examine the matter in any detail because of experimental difficulties.

The tensile stresses necessary to cause fracture in the crystals have been measured. There is a considerable scatter in the results, probably associated with the small amount of plastic deformation before fracture, usually less than 6 per cent. However, it is clear that the resolved stress perpendicular to the cleavage plane is approximately constant for all the twenty-six crystals breaking between twin and matrix, the average value being 583 gm./mm.^{2}. This is somewhat lower than the value of 695 gm./mm.^{2} determined by Wassermann[7] for 4-mm. diameter crystals of similar orientations.

It was found that in all the above twenty-six crystals the resolved stress across the most favourably orientated twin plane and in the twin direction exceeded the critical value for the growth of twins, as determined by Gyndyn and Starsev[8]. Four crystals did not show this phenomenon of separation as described above, but broke by a true cleavage on either a (111) or a $(11\bar{1})$ plane. In three of these four crystals the applied stress was not great enough to cause a twin to grow. It was interesting to note that in these crystals also the resolved stress perpendicular to the cleavage plane was less than in the main group of crystals.

Our thanks are due to Messrs. Mining and Chemical Products, Ltd., for the gift of the bismuth used in this work.

Detection of Iodine-containing Substances on Paper Chromatograms

THE most sensitive chemical method of detection of iodine-containing substances on paper chromatograms is the application of the ceric sulphate–arsenious acid reaction[1]. By the use of this method the iodine-containing substances are indicated by white spots on a yellow background. Fletcher and Stanley[2] obtained white spots on a brown background by spraying such chromatograms with 1 per cent *o*-phenylenediamine in acetone.

We added ferroine to the ceric sulphate–arsenious acid reagent to make up the final concentration of this compound to 0·01–0·0066 M. The technique of detection was the same as that described by Bowden *et al.*[1]. By using this method we have obtained red spots on a blue background. This contrasting colour reaction is stable for approximately 48 hr., and may be registered simply by direct photography.

Detection of Triterpenoid Glycosides on Paper Chromatograms

IN the course of our investigations of *Echinocystis lobata* seeds, it became desirable to locate triterpenoid glycosides on paper chromatograms by means of a colour reaction. A modification of the Liebermann–Burchard test described by Neher and Wettstein[1] was unsatisfactory for this purpose. We found that the original Liebermann–Burchard reaction applied to paper chromatograms with comparatively little alterations gave more satisfactory results, permitting a reliable detection of the spots.

The procedure is as follows. The dried paper chromatogram is placed on a glass plate and sprayed with a mixture of equal volumes of chloroform and acetic acid anhydride. A thin layer of concentrated sulphuric acid is spread on a glass plate and the treated filter paper strip laid on it. Additional sulphuric acid is smeared on the top of the strip with a glass rod. After a few minutes, the triterpenoid glycosides develop red-coloured spots. The starting line and the front, as well as the spots, can be marked on the other side of the glass plate in order to obtain the R_F values. This has to be done before the paper is destroyed by the sulphuric acid. Using Whatman No. 1 paper, after 15 min. the destruction is so far completed as to prevent the precise measurement of distances. The sensitivity of the test can be increased by examination of the chromatogram in ultra-violet light. The spots show orange fluorescence. In Table 1 are collected results, observed with pure echinocystic acid glycoside, isolated from *Echinocystis lobata* seeds. Similar results are obtained with methanolic extracts from the seeds.

The presence of the usual plant constituents (for example, oligosaccharides and amino-acids) does not interfere with the reaction. This method has been applied to the detection of triterpenoid compounds of several plants known to contain triterpenes[3]. Ethanolic extracts (70 per cent v/v) were chromatographed with butanol/acetic acid[2] and the chromatograms treated as described above. The results are shown in Table 2.

Table 1. PAPER CHROMATOGRAPHY OF ECHINOCYSTIC ACID GLYCOSIDE

Separation of Pyridine Mono-Carboxylic Acids on Paper Chromatograms

CHEMICAL methods using cyanogen bromide and aromatic amines[1-3] (König reaction) and an acid-indicator[4] for the detection of pyridine carboxylic acids on paper chromatograms have been reported. But the toxic character of cyanogen bromide causes difficulty ; and it has been observed that good spots with acid-indicator are often not produced, particularly when the acid concentration is very low. A very convenient method has been found for detecting these acids on the filter paper by spraying with a solution containing cupric ions followed by benzidine; also their efficient separation from the mixture has been achieved.

In our experiments α-, β- and γ-pyridine carboxylic acids were used individually or as a mixture. The paper (Whatman No. 1 ; 15 cm. × 24 cm.) after development (ascending technique) for 4–6 hr. at 30 ± 0·5° C. with the solvent (as described in Table 1) was completely dried by a current of hot air. It was next sprayed with a 0·2 per cent solution of copper sulphate (anhydrous) in a water–ethanol mixture (5 : 4, by vol.) and dried carefully in an oven kept at about 60° C. The dried paper, on spraying with a 0·1 per cent solution of benzidine in 50 per cent ethanol, revealed well-defined bluish spots against a light-brown background. 10–15 μgm. of each component acid could be separated and detected on the chromatogram.

Copper salts, for example, sulphate, chloride, acetate, etc., have been employed as detection reagents ; but copper sulphate has given the most satisfactory result. Butanol with a mobile phase acidified with acetic acid gives the best separation and also raises the respective R_F values when compared to butanol alkalized with ammonia[1]. The other solvent systems studied produced high R_F values but contributed little towards resolution. Better results are given when the chamber is maintained fully saturated with respect to the solvent system.

Table 1. R_F VALUES OF PYRIDINE CARBOXYLIC ACIDS

Substance	Solvent			
	n-Butanol/acetic acid/water (4 : 1 : 1)	*n*-Butanol saturated with 1·5 *N* ammonia	*n*-Propanol conc. ammonia water (20 : 1 : 4)	Phenol saturated with water
Picolinic acid	0·63	0·15	0·57	0·56
Nicotinic acid	0·89	0·21	0·61	0·88
*iso*Nicotinic acid	0·76	0·22	0·67	0·90

We wish to thank Prof. S. K. Bhattacharyya for his interest and encouragement. Our thanks are also due to Messrs. Sarabhai Chemicals for a gift of *iso*-nicotinic acid.

A Simple Method of *Rh* Determination

IT has been shown that about 0·5 per cent of human sera possess a thermostable factor agglutinating *O Rh*+ red cells sensitized with anti-*D* antibodies. Only those sera were taken into account which agglutinated sensitized red cells at least in 1 to 8 dilution in saline. Weaker sera gave unreproducible reactions. The strongest serum observed had a titre of 128. According to our experiments[1], the agglutinating factor in the sera observed is an antiglobulin antibody. It may be absorbed from the sera by sensitized red cells and it may be neutralized in the sera by incomplete antibodies regained at 56° C. from cells. This antiglobulin antibody reacts only with immune antibodies after their denaturation in serological reaction, and therefore it is not neutralized by normal serum or by immune serum containing unchanged antibodies (Fig. 1). The discussion on the nature of this antibody and on its eventual role in pathology will be given elsewhere. Here we wish to stress the practical application of our findings.

(1) A 3 per cent suspension of red cells sensitized with incomplete antibody was tested with human antiglobulin sera. Cells sensitized with all anti-*D* sera gave strongly positive reactions. Tests performed with other incomplete antibodies gave various results depending only upon the strength of the sensitization and not upon the specificity of antibody used. Since the human antiglobulin antibody is not neutralized by serum proteins (other than denatured antibody) the washing of sensitized cells can be omitted.

(2) *Slide agglutination test with mixed serum.* All the incomplete sera may be easily changed into saline agglutinating sera simply by mixing with human antiglobulin sera. After preliminary experiments, the following technique was adopted. Undiluted antiglobulin serum is mixed in equal proportions with undiluted incomplete anti-*Rh* serum. To one drop of mixed serum on a slide is added one drop of 3 per cent saline suspension of red cells with corresponding *Rh* antigen. The slides are allowed to stay in a wet chamber at room temperature for 20–30 min., after which clear-cut results are obtained. The agglutination is a very firm one and does not disappear after vigorous shaking.

In this manner fifteen anti-*D*, three anti-*c*, one anti-*C* and one anti-*e* incomplete sera have been tested. In all cases the mixed serum gave the expected reactions. The controls with cells of non-corresponding *Rh* types were always negative. The titre of a mixed serum was 4–16. The mixed serum can be stored frozen for at least five months. This method of *Rh* determination is much simpler than any other used.

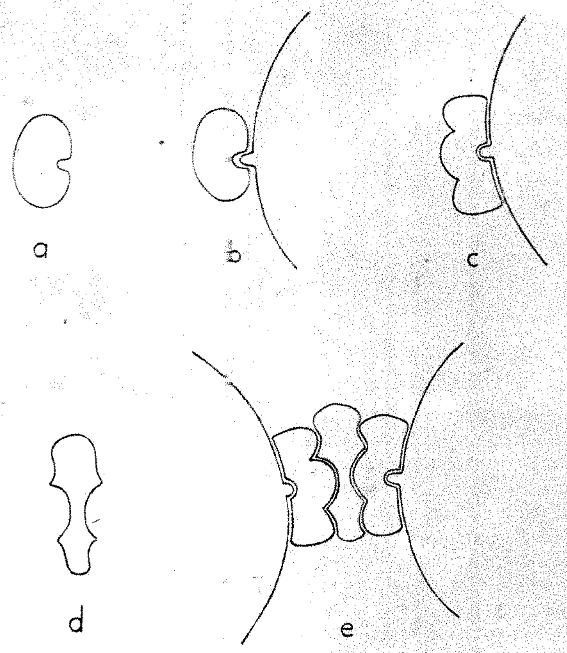

Fig. 1. (*a*) Incomplete antibody; (*b*) serological linkage with red cells; (*c*) denaturation of the antibody molecule in reaction with antigen; (*d*) human antiglobulin antibody; (*e*) agglutination of sensitized red cells

(3) *Antiglobulin test with platelets.* The chief difficulty in carrying out the antiglobulin test with platelets (and also leucocytes) is the necessity of saline washing, which causes clumping of these cells. With our human antiglobulin sera, washing can be omitted. Our preliminary experiments are promising.

While our investigation was in progress, we saw the interesting paper in *Nature* of Lewis and Chown[2]. It is now clear that these authors were using a very weak human antiglobulin sera. Therefore they obtained agglutination with mixed sera and could produce this phenomenon only with some anti-*Rh* sera. The negative results with sensitized cells made impossible a correct interpretation of the results.

Carnosine Phosphate as Phosphate Donor in Muscular Contraction

CARNOSINE phosphate was first synthesized by Severin, Georgievskaya and Ivanov[1] by a method very similar in detail to that for creatine phosphate[2]. They showed that this method yields as a rule a diphosphate, both phosphate bonds being high-energy; but that the one which is not on the imidazole ring is more labile. In the presence of muscle extract the latter is transferred to adenosine diphosphate.

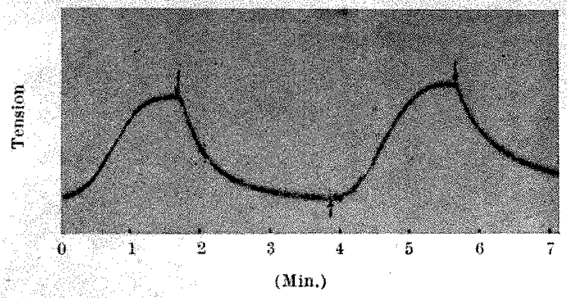

Fig. 1. Isometric tension of extracted muscle fibre in solution containing carnosine phosphates equivalent to 30 millimoles of phosphorus and 4 millimoles of magnesium chloride. ↑ pH 7, ↓ pH 6

In another direction it has been shown by a number of workers[3-5] now that transphosphorylation to adenosine diphosphate is an essential, though not in itself sufficient[6], part of the relaxation mechanism in muscle. Furthermore, the possibility of an unidentified phosphate donor has been noted[7] in connexion with the failure to observe an increase of adenosine diphosphate during a muscle twitch.

Carnosine phosphate was prepared by the method of the Russian workers. The measured N/P showed that a 50 per cent mixture of di- and mono-phosphates was obtained. A solution containing 30 mM phosphorus final concentration was tested by the method of Goodall and A. G. Szent-Györgyi[8] for the relaxing action of creatine phosphate on the glycerol-extracted muscle fibre. The results indicated in Fig. 1 show an effect practically identical with the latter.

The result strongly supports the claim of the Russian workers and raises the question of the presence and role of this substance in muscle. All muscles contain carnosine or anserine (in which the less labile phosphate site is occupied by methyl) in amounts up to 20 mM. It was noted in the course of phosphorus-determination that carnosine phosphate is much more acid-labile than creatine phosphate. This may account for its non-detection in muscle so far.

This work was aided by a grant from Muscular Dystrophy Associations of America, Inc., to Dugald E. S. Brown.

Appearance of Serine upon Alkaline Incubation of Iodinated Polytyrosine

3,5-DIIODOTYROSINE is known to be a precursor of thyroxine[1,2]. The formation of thyroxine from two diiodotyrosine residues leads obviously to the formation of a three-carbon α-amino-acid. Thus simple dismutation would lead to alanine[2,3], while an oxidative mechanism involving the formation of a labile intermediate of quinonic structure should yield serine[1,2,4]. In the latter case, serine could be formed either by the direct hydrolysis of the labile intermediate[4], or by the hydration of dehydroalanine formed upon molecular dissociation of the labile intermediate[1]. If the unsubstituted 3,5-diiodotyrosine is used in the reaction, dehydroalanine formed may also be hydrolysed to pyruvic acid and ammonia. Johnson and Tewkesbury identified these two products in their reaction mixture[4]. Pitt-Rivers identified alanine among the products of the aerobic incubation of N-acetyl-L-diiodotyrosine chromatographically, but stated that alanine could have been formed afterwards from pyruvic acid[5].

Iodinated polytyrosine was chosen for the re-investigation of the products of alkaline incubation of diiodotyrosine present in a peptide chain. The high-molecular weight compound seemed suitable for this purpose, as it was expected that the high local concentration of diiodotyrosine residues in the macromolecule might facilitate the reaction between the residues. Furthermore, the protection of both the carboxyl- and the amino-group of 3,5-diiodotyrosine is known to increase the yield of the reaction[2,5].

Poly-L-tyrosine[6] (number average degree of polymerization 30) was iodinated with 0·2 mole of iodine per mole of tyrosine residue, using the iodination technique described previously[6]. The iodinated polymer was hydrolysed with 6 N barium hydroxide for 8 hr. at 120°, and the barium was removed as barium sulphate. A paper chromatogram (n-butanol/glacial acetic acid/water, 25 : 6 : 25) of the hydrolysate showed on spraying with ninhydrin three spots, identified as tyrosine, monoiodotyrosine and diiodotyrosine.

A 1 per cent solution of the iodinated polymer in a bicarbonate buffer pH 10·2 was incubated at 37° for a week. The polymer was precipitated with hydrochloric acid and hydrolysed as above. Paper chromatograms (n-butanol/glacial acetic acid/water, 25 : 6 : 25) of the hydrolysate showed on spraying with ninhydrin six spots: the three original spots (tyrosine with R_F 0·36, monoiodotyrosine with R_F 0·58 and diiodotyrosine with R_F 0·66), as well as three new spots, one with R_F 0·17 travelling identically with serine, one with R_F 0·80 travelling identically with thyroxine or 3,5,3′-triiodothyronine, and a faint spot with R_F 0·73. Alanine moves in the chromatographic developer mixture used with R_F 0·23, and in a mixture of alanine with the hydrolysate investigated the spot of alanine could be clearly separated by chromatography from the spot corresponding to serine. Treatment of the chromatogram of the hydrolysate with cerium sulphate–sodium arsenite[7] showed that the compounds travelling with R_F values of 0·73 and 0·80 contain iodine. The hydrolysate was developed also in n-propanol/water/concentrated ammonia (100 : 50 : 1) and in water-saturated phenol, and in both cases the chromatograms showed a spot moving identically with serine. In order to confirm the identity of serine on the chromatograms, a larger amount of the hydrolysate was chromatographed and the band corresponding to serine was eluted. A specific serine-requiring mutant *E. coli* K$_{12}$W–1977, kindly supplied by Dr. J. Lederberg, assayed on a minimal medium described by Tatum and Lederberg[8], responded to the concentrated eluate.

It can be seen from the above that serine, but no alanine, is formed during the alkaline incubation of iodinated polytyrosine. The spots moving with R_F values 0·73 and 0·80 are probably iodinated thyronines.

Similar experiments have been carried out on poly-L-tyrosine samples of average degrees of polymerization 8 and 50, iodinated with 0·2 and 0·7 mole of iodine per mole of the tyrosine residue respectively. A polymer composed on the average of fifty α-amino-acid residues, of which 14 moles per cent were tyrosine, 20 moles per cent were monoiodotyrosine and 64 moles per cent were diiodotyrosine, contained after incubation 2 moles per cent of serine in the hydrolysate. The amounts of the various α-amino-acids were determined by quantitative ninhydrin colorimetry after chromatography.

We wish to thank Dr. Rosalind Pitt-Rivers for helpful suggestions and for samples of thyroxine and 3,5,3′-triiodothyronine, and Prof. E. Katchalski for his continued interest in this work.

Effect of L-Thyroxine on Carotene and Vitamin A Metabolism in the Cow and the Chick

IT has long been known that vitamin A metabolism is related to the functioning of the thyroid gland[1-3]. The relation between thyroid hormone and fæcal excretion of ingested carotene has been demonstrated by Cama and Goodwin[4] in the rat, and by Chanda *et al.*[5] in the cow and the goat. The effect of the thyroid on the storage of dietary carotene as vitamin A in the liver of rats has also been demonstrated[3]. Chanda and Owen[6] studied the changes in the carotene and vitamin A content of cow and goat milk as effected by parenteral administration of DL-thyroxine. More recently, Chanda, Clapham and Owen[7] have reported their findings on the effect of anterior pituitary thyrotrophic hormone on the simultaneous changes in the partition of carotenoids and vitamin A in the blood serum and the milk of cows.

Since the development of new methods for the synthesis of crystalline L-thyroxine by the Glaxo Laboratories, Ltd., the galactopoietic action of the hormone has been studied by British workers[8]. The present communication reports briefly the effects of synthetic L-thyroxine on carotene and vitamin A metabolism in the cow and the chick.

Two experiments were carried out. In the first, six cows of the Hariana breed were divided into three groups of two each, and the experiment was divided into four periods, the first and last of which served as control periods. Each of a pair of cows received daily by mouth 6 gm. L-thyroxine triturate during period (2), and 8 gm. during period (3). A second pair each received parenterally 7·5 mgm. and 10 mgm. DL-thyroxine per day during periods (2) and (3) respectively. The remaining pair served as controls; but one of them received 6 gm. and 8 gm. lactose per day during periods (2) and (3) respectively, while the second cow received 10 ml. normal saline per day during periods (2) and (3). The hormone was also administered parenterally in 10 ml. solution prepared according to the method of Chanda and Owen[6].

In a second experiment, groups of one-week old chickens of Rhode Island Red and White Leghorn breeds were for eight weeks given a feed mixture containing the hormone; one group received 1 gm. L-thyroxine triturate per 10 lb. feed, and a second group received 20 mgm. DL-thyroxine (mixed in 980 mgm. lactose) per 10 lb. mixture. The diet of the third group of birds, which acted as controls, contained an equivalent amount of lactose only. The triturate contained 1 per cent L-thyroxine. There were ten birds of each breed in each group. Two birds of each breed from each group were killed on the day the feeding of experimental diet started, and, thereafter, at intervals of two weeks. Samples

* One-week old chicks at the commencement of hormone treatment.
† After 8 weeks of hormone treatment.

of blood, liver and intestine from individual birds were analysed separately for carotene and vitamin A.

The partition of carotenoids and vitamin A in milk, blood and other tissues was carried out by the method already described by me and my associates[6,10,11] at the Hannah Dairy Research Institute.

Cows. L-Thyroxine administered orally caused an increase in the β-carotene and vitamin A ester content of the milk fat of Hariana cows in much the same way as was observed previously in the milk fat of Ayrshire cows treated with DL-thyroxine parenterally[6]. It was further observed in the present experiment that the β-carotene and vitamin A ester content of blood serum increased during thyroxine treatment, and that the increases in milk and blood vitamin A ester were greater when the hormone was given orally than when it was given parenterally (Table 1). As no preformed vitamin A was present in the diet of the cows, the latter effect was due probably to greater conversion of dietary carotene into vitamin A in the intestines (see experiment with chicken). The increases in the β-carotene content in the blood (Table 1) and milk due to hormone treatment were greater in cows treated parenterally than in cows which received the hormone orally.

The vitamin A alcohol content of both the milk and blood serum lipids remained fairly constant, except during noticeable hyperthyroidism during period (3), when increases occurred only in the cows treated with hormone. It was further observed that the effects of thyroxine on carotene and vitamin A metabolism were independent of the responses in the milk yield.

Chicken. Vitamin A ester contents of blood and liver determined at two-week intervals showed a gradual increase with age in all the groups, but the rate of increase was accelerated by the hormone treatment. The vitamin A alcohol levels in the blood were also built up at a greater rate in the birds treated with hormone than in the control birds. This is evident from Table 2, in which only the initial and final value for Rhode Island Red birds are recorded for the sake of brevity.

In order to find out whether the greater concentrations of vitamin A in the birds treated with hormone were due to greater conversion of carotene to vitamin A in the intestine, an experiment was carried out in which twelve Rhode Island Red birds were divided into two groups of six each. Both groups received a carotene-free and vitamin A-free ration, but one group received 1 gm. L-thyroxine per 10 lb. feed mixture. The birds were initially four weeks old; the dietary and hormonal treatment were given for four weeks. After the treatment period, two birds of each group received 1 gm. arachis oil only, while the remaining four birds received 10 mgm. β-carotene in 1 gm. arachis oil. The birds were killed 4 hr. after the meal of β-carotene, and the different segments of the intestines were analysed by the methods of Thompson, Ganguly and Kon[12].

The results recorded in Fig. 1 show that the birds treated with thyroxine converted orally administered β-carotene into vitamin A at a higher rate in their small intestines than the controls which were denied the hormone treatment. It seems reasonable to suppose that the greater concentrations of vitamin A in the blood and liver of the treated birds were due mainly to greater conversion of carotene into vitamin A in the intestines (Fig. 1).

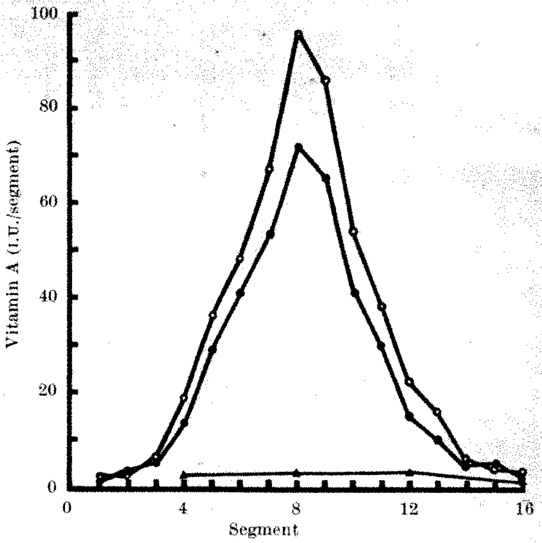

Fig. 1. Vitamin A in the wall of sixteen segments of the small intestine of vitamin A-deficient Rhode Island Red chicks 4 hr. after a meal of 10 mgm. β-carotene in 1 gm. arachis oil (80–90 per cent of the vitamin A was present as vitamin A ester). ○——○, L-thyroxine-treated chick dosed with β-carotene in arachis oil; ●——●, control chick dosed with β-carotene in arachis oil; ▲——▲, L-thyroxine-treated chick dosed with arachis oil (four segments only). Each point in the curves indicates the mean value for four chicks, except that two chicks were dosed with arachis oil only (see text)

The physiological and biochemical significance of these findings will be discussed when full accounts of these and other experiments, which are in progress, are published.

I wish to thank Dr. L. C. Sikka for his interest in this work and Mr. P. B. Sen for permission to use the Unicam *SP*500 spectrophotometer in the Laboratory of the Department of Physiology, University of Calcutta. Thanks are also due to Dr. T. F. Macrae, of Glaxo Laboratories, Ltd., for a generous gift of synthetic sodium L-thyroxine triturate.

Fluorescence of Adrenaline and Noradrenaline with Ethylene Diamine

Weil-Malherbe and Bone[1] claimed to have estimated the relative proportions of adrenaline and noradrenaline in mixtures of the two by the different colours of fluorescence given by these substances when coupled with ethylene diamine and extracted into *iso*-butanol. We attempted to repeat this work but obtained varying results. We therefore investigated further the mechanism of the reaction.

Oxidation is an essential preliminary: for this, oxygen or other oxidizing agents such as manganese dioxide or potassium ferricyanide may be used; it is not sufficient to rely on the air dissolved in the solutions. Too high a pH at this stage reduces the yield of the fluorescent products.

The reaction proceeds in several steps; the relative rates of formation and decomposition of the intermediate products depend on temperature, pH and concentration of ethylene diamine.

The first step is the development of a substance having an absorption maximum at 350 mμ. This substance is not fluorescent or appreciably extracted by butanol. Optimum conditions for its formation are pH 9·5, ethylene diamine concentration 0·4 per cent (v/v); the yield is maximal in 15 min. (see Fig. 1).

At higher concentrations of ethylene diamine, this substance forms and decomposes rapidly: it gives rise to another substance with an absorption maximum at 405 mμ; an *iso*bestic point is shown at 370 mμ (see Fig. 2). This material is fluorescent and is extracted by butanol, in which solvent it has an absorption maximum at 415 mμ. The optimum conditions for its formation are pH 11 and an ethylene diamine concentration of 5 per cent (v/v); at pH 10 or 12 the maximum absorption at 405 mμ is only about 60 per cent of that obtained at pH 11. The optimum temperature is between 50° and 70° C., the yield being maximal in 1·5–2 hr. Higher concentrations of ethylene diamine make little difference other than to shift the absorption maximum slightly towards a longer wave-length.

This substance with absorption maximum at 405 mμ is comparatively stable. At higher temperatures, higher pH, or on prolonged incubation it decomposes to give rise to a product having an absorption maximum at 330 mμ, which is also fluorescent.

Finally, we examined the butanol extracts of the noradrenaline and adrenaline derivatives of ethylene diamine prepared under the conditions which gave the maximum amounts of the substance having an absorption maximum at 405 mμ. These extracts were chromatographed both on filter paper (Whatman No. 1) and on cellulose powder columns; they were developed with water-saturated butanol. A similar result was obtained with either method.

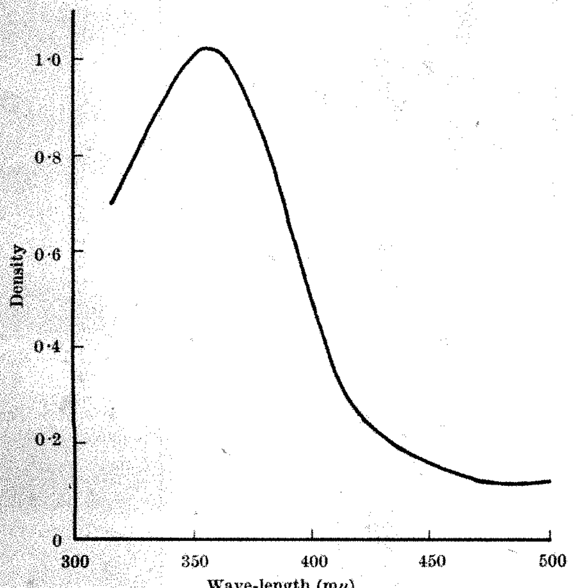

Fig. 1. Absorption spectrum of product having extinction maximum at 350 mμ.
Ethylene diamine 0·4 per cent (v/v) adjusted to pH 10·1 with sulphuric acid. Noradrenaline 10·0 μmoles per 100 ml. Solution saturated with oxygen and incubated at 50° for 16 min.

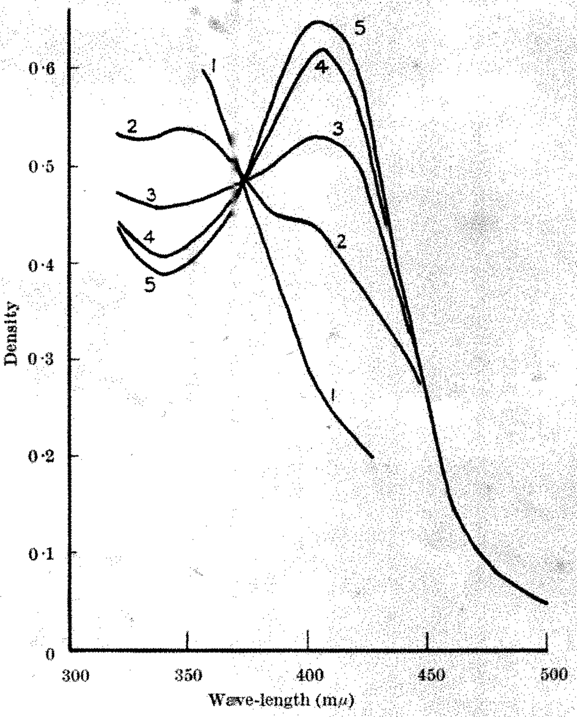

Fig. 2. Time-course of the reaction between ethylene diamine and noradrenaline.
Temperature 51°. Ethylene diamine 3·3 per cent (v/v) adjusted to pH 11 with sulphuric acid. Oxygen bubbled through the solution continuously, evaporation being prevented by a reflux condenser. Noradrenaline 7·0 μmoles per 100 ml. added at zero time.
Curve (1), 10 min.; (2) 21 min.; (3) 35 min.; (4) 58 min.; (5) 130 min.

The noradrenaline derivative separated into two fractions: the greater part, R_F 0·64, fluoresced bluish-green; the lesser part, R_F 0·24, fluoresced yellow. The adrenaline derivative also separated into two fractions: the greater part, R_F 0·37, fluoresced yellow; the lesser part, R_F 0·69, fluoresced green.

We have also obtained evidence from the emission spectrum of the noradrenaline derivative that the proportions of the two fluorescent products depend on the concentrations of noradrenaline and of ethylene diamine.

We conclude that there must be at least two fluorescent derivatives of noradrenaline and adrenaline, and that in order to obtain reproducible results the conditions must be very carefully controlled.

We are indebted to Mr. J. R. P. O'Brien for his direction, and Mr. G. Newman for his assistance.

Spore-like Structures in the Tubercle Bacillus

ELECTRON microscopy of ultra-thin sections of avian tubercle bacilli growing on various solid media has revealed details of their internal anatomy. In the initial phase of growth, the structure was similar to that described in the ordinary bacteria[1-3]. Each rod contained a central dense core in the form of a thread or group of granules within an electron-transparent area (Fig. 1). This structure is believed to represent the nuclear apparatus. There appeared to be some correlation between the phase of growth of the bacillus and the configuration of the dense core. When division by transverse fission took place, each daughter cell contained its own nuclear apparatus. The cytoplasm of the avian tubercle bacilli showed certain differences from the bacteria, and contained large, fairly dense granules (300 A.); but the general pattern of reproduction appeared to be the same.

In later stages of development, under certain conditions, the avian bacilli had a very different internal structure. When grown as slide cultures on thin chicken plasma–embryo extract clots, they did not all divide directly by transverse fission; some of them elongated into filaments, and round bodies were observed forming in the cytoplasm. At first these bodies were difficult to distinguish from the remainder of the cytoplasm; but later they were clearly seen. The nuclear apparatus was still present during the early stages of the formation of the round bodies and was quite distinct from them. The number of round bodies increased until they filled the whole filament except for a peripheral region which contained cytoplasmic granules and dense, metaphosphate bodies (Fig. 2). The round bodies were of uniform internal density and each was enclosed in a dense outer membrane. During the final stages of development some of the filaments contained large vacuoles which appeared to be associated with the formation of the round bodies. Cross-walls were present dividing the filaments into sections each of which contained two or more dense bodies.

In previous studies of unsectioned avian tubercle, rows of vacuoles[4] or intracellular units[5] of varying density and with sharply defined membranes were observed. The interpretation of these units presented some difficulties. They varied in density and were certainly not sap vacuoles as suggested by Knaysi, Hillier and Fabricant[6]; nor could they be identified with the protoplasts[7] of other bacteria, as they were embedded in the cytoplasm. The most likely assumption seemed to be that they were spores, and this was suggested[5]. Our observations on thin sections support this interpretation. From a recent paper by Chapman[8] on spore formation in *Bacillus cereus* and *Bacillus megaterium*, it is seen that the spores in these organisms are strikingly similar to the round bodies in the avian tubercle bacilli.

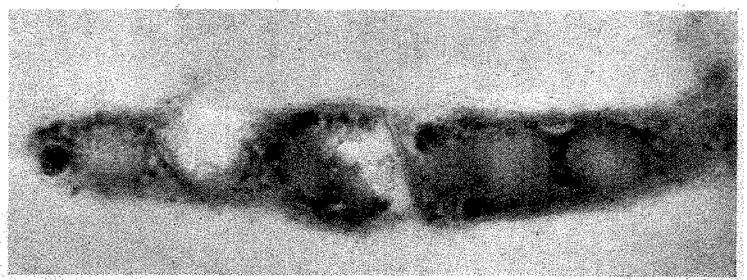

Fig. 2. Dividing filament containing row of spore-like bodies. Note cytoplasmic granules surrounding spores. × 40,000

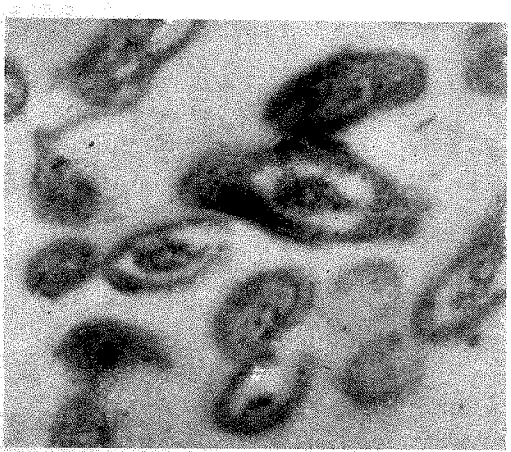

Fig. 1. Elongating rods with central vacuole containing dense structures (nuclear apparatus). Cytoplasmic granules. × 35,000

From this evidence it is suggested that under certain conditions the avian tubercle bacillus produces spores. In future experiments the spore-like bodies will be isolated and their subsequent behaviour studied to test the accuracy of this hypothesis.

We are indebted to Dr. V. E. Cosslett and Mr. R. W. Horne, of the Cavendish Laboratory, Cambridge, for providing electron microscope facilities.

Effect of Electrolytes on the Rate of 'Supercontraction' of Wool Fibres

WOOL fibres have been shown to shorten (supercontract) when held in steam and rapidly stretched and relaxed, or when treated with hot solutions of reagents breaking disulphide bonds, with cold solutions of metal ammonium hydroxides, or with hot solutions of formamide, certain phenols, or lithium bromide (see Alexander and Hudson[1]).

The effects of phenols, formamide, metal co-ordination complexes, and lithium bromide have been attributed to the rupture of hydrogen bonds, and the effects of most other treatments to splitting of disulphide cross-links. Alexander[2] suggests that lithium ions, being small and having high polarizing power, would be able to combine with polarizable groups of the proteins when the ions are sufficiently concentrated to be incompletely hydrated. He adduces, in support of this theory, the very great increase in rate of supercontraction with increasing concentration of lithium bromide at concentrations corresponding to about ten molecules of water per lithium ion.

In order to gain greater insight into the mechanism of supercontraction in lithium bromide solutions, wool fibres have been immersed in concentrated solutions of various salts buffered at *p*H 6·5–7·0 with 0·1 *M* tartrate or phosphate, maintained for 1 hr. at 100° C., and changes in length measured. Corriedale 56's wool, cleaned by rinsing repeatedly with cold light petroleum, cold ethanol and water, was used for these experiments. The cations investigated were potassium, sodium, lithium, calcium, strontium and beryllium, and the anions, acetate, chloride, bromide, iodide, thiocyanate, trichloracetate and benzoate; supercontraction was obtained with salts containing each of these ions, and several salts, notably lithium and calcium iodide, were more effective than lithium bromide.

The observation by Miss June Griffith (unpublished) that the presence of free halogen in the halide solutions inhibits supercontraction has been confirmed. Removal of free halogen with thiosulphate resulted in supercontraction of the wool at lower salt concentrations and gave greater uniformity of the results.

Curves relating the amount of supercontraction of wool to the concentration of reagent have been constructed for each salt. On arranging the salts of a particular cation in order, according to the concentration required to bring about a certain degree of supercontraction, for example, 25 per cent, the anions have been found to occur in the order of the lyotropic series. With lithium salts the approximate concentrations required for supercontraction of this order were: acetate, $> 12\,M$; chloride, 8·5 *M*; bromide, 4·5 *M*; iodide, 3 *M*. With a series of iodides the concentrations required were: potassium, 6 *M*; sodium, 5 *M*; lithium, 3 *M*; strontium, 3·5 *M*; calcium, 2 *M*.

The results resemble those obtained by Lennox[3] and Jordan Lloyd and Garrod[4] when investigating the effects of a similar series of salts on the thermal shrinkage of collagen. As collagen contains no disulphide linkages and the salts investigated have no known reaction with cystine or its peptides, it is reasonable to conclude that the primary reaction with wool does not involve disulphide bonds but is similar to the denaturation of soluble proteins. The demonstration by Beauregard, Brown and Harris[5] that cross-linking with ethylene dibromide did not prevent supercontraction of wool with lithium bromide also emphasizes this fact.

The above results invalidate Alexander's[2] explanation of the action of lithium bromide, since 3 *M* lithium iodide, which is as effective as 5 *M* lithium bromide, contains about seventeen water molecules per cation; also it is unlikely that sodium and potassium ions form complexes with proteins in the manner suggested for lithium ions. An alternative explanation is possible if the tendency for ions to be adsorbed on the wool proteins varies in much the same way as their tendency to become adsorbed on non-protein colloids and on carbon, the small highly hydrated ions being adsorbed least readily and the large, less hydrated ions being adsorbed most readily. The effective molecular charge of a negatively-charged protein would then tend to increase in the presence of high concentrations of a salt of a readily adsorbed anion and a cation which is not readily adsorbed. Any marked increase in molecular charge of the wool proteins would impose stresses on intramolecular and intermolecular bonds, resulting in disaggregation and disordering of the wool proteins. In this regard the effect would be similar to that of anionic wetting agents on the intercellular proteins of the wool cortex[6].

Cytotaxonomy and the Migration of Primitive Peoples

A FEATURE of the island-to-island migrations of Polynesian and other Pacific races is that the natives carried with them certain of their cultivated food plants and established them in their new settlements. Some of the original plantations have survived until the present day, and it may be possible to trace the paths of early human migration through a study of the distribution of the food plants.

Certain species of taro (*Colocasia antiquorum* Schott and the closely related (if not synonymous) *C. esculenta* Schott) seem particularly suitable for cytological study since they do not flower readily in many localities and rarely, if ever, appear to set viable seed. The method of propagation is to cut off the base of the rootstock (which is eaten) and replant the upper portion which includes both roots and shoot. Less frequently, in certain varieties, clonal segregates are obtained. Because of these exclusively asexual reproductive modes, the chromosome number is likely to remain constant over long periods.

While the majority of varieties studied to date (some sixty in number) have a diploid chromosome number of 28, the triploid figure of 42 has occasionally shown up. Of particular interest is the fact that a 42-chromosome variety has been found in New Zealand, in a locality (Cavalli Islands) and in circumstances which strongly suggest that it has survived there since the earliest known Maori settlement. A preliminary examination of some twenty varieties from the Polynesian region of the Pacific has failed to bring to light any triploid types. On the other hand, as a result of recent investigations in New Caledonia, two varieties were found with 42 chromosomes.

While it is too early to draw any conclusions from these findings, it is interesting to note that 42 chromosomes have been recorded independently by Japanese and Indian cytologists for the variety *gigantea*. With no evidence so far to the contrary, it is not inconceivable that the New Zealand variety has derived from a south-east Asian source via the Malayan Peninsula and the chain of islands to the south and east.

It must be stressed, however, that the bearing of such evidence, alone, on the origins of the Maori cannot extend beyond the nearest neighbouring island in a chain of this sort, since it is entirely within the realms of possibility that the Maori acquired the taro while *en route* from a totally different area of the Pacific. Nevertheless, by an extension of the method (since presumably the forerunners of the Maori carried comparable food plants in prior migrations) it may be possible to trace the origin of this and other racial groups progressively farther and farther back into prehistorical times. Further studies along these lines are being planned, utilizing in addition other species of taro (*Xanthosoma*, *Alocasia*, *Cyrtosperma*) as well as *Ipomoea* spp. (sweet potato and kumara) and the yam (*Dioscorea*).

Histamine of the Reptilian Stomach and Lung

WRIGHT *et al.*[1] have demonstrated that the stomach of *Testudo graeca*, *Tachysaurus rugosus* and *Tiliqua nigro-lutea* secretes hydrochloric acid and some pepsin in response to large doses of histamine but is only slightly responsive to vagal stimulation. The histamine concentration of the stomach of *Tiliqua nigro-lutea* (closely related to *Tachysaurus*) was therefore investigated in November 1955. The full thickness of stomach of one lizard was cut up, after scraping off contents, and boiled in Tyrode. The concentration of histamine on titration was 75 μgm./gm., which is a high level.

Histamine was demonstrated in the Tyrode-boiled extract by assay on the isolated jejunum of the guinea pig suspended in Tyrode, before and after treatment with anti-histamine. when the response of equivalent doses of histamine always equalled that of the titrated stomach extract. Assay on the systemic blood pressure of the atropinized cat confirmed the concentration exactly. Further, paper chromatography with two solvents (propyl alcohol–acetic acid–water and butyl alcohol–acetic acid–water) yielded equal runs with pure histamine hydrochloride and stomach extract, one run of which is illustrated in Fig. 1.

Extract for the chromatography was obtained by the modified method of Code[2] for histamine extraction of the whole stomach of another lizard which contained a comparable amount of histamine. Barger and Dale[3] found 19 μgm. histamine/gm. in the intestinal mucosa of the ox, Kellaway and Trethewie[4] a maximum of 48 μgm. histamine/gm. in the whole perfused gut of the guinea pig, and unsqueezed adult guinea pig lung (Australian) contains usually 20–40 μgm. histamine/gm. [5].

The lungs of these reptiles showed no evidence of histamine in them, only a 'slow-reacting' substance like that described by Kellaway and Trethewie[4] or 'slow-contracting substance'[6,7].

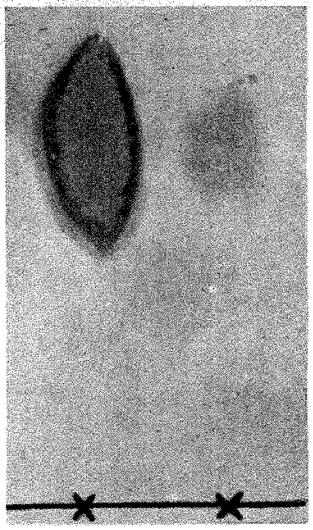

Fig. 1. Chromatogram of lizard stomach extract compared with histamine dihydrochloride, with propyl alcohol – acetic acid – water solvent

The paper chromatography was kindly performed by Mr. Peter Morgan.

A Case of DDT Poisoning in Fish

A SERIES of experiments were conducted at Khartoum by a private company concerning the control of *Tanytarsus lewsii*, a green chironomid. During these experiments, a section of the Blue Nile was sprayed by air at Soba Village about ten miles above Khartoum, with an emulsifiable oil containing 30 per cent DDT and 0·5 per cent 'Lissapol'. The equivalent of 440 lb. DDT was sprayed over an area in order to give a calculated DDT content of 0·09 p.p.m. It was hoped that by the time treated water reached Khartoum, the DDT concentration would have been diluted four times. The concentration of DDT at the time of arrival at Khartoum was 0·017 p.p.m. and was then maintained at a level of 0·003 p.p.m. for six hours.

The same day, it was reported that "hundreds of fish were found dying" at Burri Village about two miles above Khartoum, at about the time the treated water was expected to arrive there. Two of these fish were brought to these laboratories on the following day. Prior to chemical examination, they were submitted to Dr. Rzoska, of the University College Khartoum, for post-mortem examination, who reported the following findings :

"The dead fish was a specimen of *Labea* sp., a plant feeder. The gills were almost white.

"The dying fish was a specimen of *Synodontis schall*, a carnivorous bottom feeder. It was severely bloated.

"The sudden appearance of a large number of dead fish of different species at the same time points to poisoning as the cause of death, and not to disease."

The two fish were then examined for the presence of DDT in different organs using the method of Schechter *et al.*[1] after a preliminary separation of the DDT from the fatty matter using the method of Schechter *et al.*[2]. The following results were obtained :

Fish	Organ	Weight taken (gm.)	Weight DDT found (μgm.)	DDT in organ (p.p.m.)
Labea sp.	gills	4·32	4	0·9
	viscera	14·26	36	2·5
	flesh	12·33	nil	nil
Synodontis schall	gills	7·04	19	2·7
	viscera	26·29	2,080	79
	fatty deposit	1·37	87	64

These results lend some support to previous work showing that fish are highly sensitive to DDT, and that non-fatty animals are more sensitive than fatty animals (summary in Hinton[3]). The *Labea* was found dead some eight hours after spraying, whereas the *Synodontis* survived thirty-six hours.

However, the possible effect of the surface-active agent should not be overlooked.

Occurrence of Paracolon Bacteria in a Tropical Marine Environment and their Classification

LATE or non-lactose fermenting bacteria are of wide interest in the clinical field because of their association with gastroenteritis and urinary infections. Because they form colourless or white colonies on coliform differential media, they are usually overlooked during the isolation of coliforms. Clemesha[1] was probably the first to recognize the importance of these organisms in India, when he stated that "a class of organisms which ferment glucose but not lactose is not only exceedingly common in water . . . but the significance of these bacteria is of great importance to the water analyst". Topley and Wilson[2] also felt that "there seems no doubt that they are a more common constituent of normal intestinal flora under tropical than under temperate conditions". In India these 'Paracolon' bacteria are misclassified in the genus *Escherichia* or *Aerobacter* despite the fact that lactose fermentation is a fundamental characteristic of the latter organisms. Topley and Wilson[2] defined 'Paracolons' as those which do not ferment lactose or ferment it slowly and have the 'IMViC' reaction $++--$. Stuart *et al.*[3] suggest the term 'Paracolon' for papillæ-forming anaerogenic and slow lactose-fermenting *Escherichia*-like organisms associated with gastroenteritis. Breed *et al.*[4] have accorded generic rank to *Paracolobactrum*, including them as an appendix to the tribe Escherichiae.

While working on the coliform types in green mussels[5], we isolated some 'paracolons' also. Two are similar to *Paracolobactrum aerogenoides*, whereas eight others belonged to *Paracolobactrum coliformae*. Three of these were malonate-positive but differed from those of Schaub[6]. All the cultures fermented glucose and all but one fermented sucrose. Dulcitol was not fermented by any of them whereas a few fermented adonitol. Gelatin liquefaction was not common, neither did many produce hydrogen sulphide. Lactose fermentation was mostly negative and very delayed if positive. All the *Escherichia*-like paracolons produced indole, in agreement with the findings of Kligler[7] and Ferguson and Wheeler[8]. Though *MR*-positive coliforms ferment glycerol, only two of the *Paracolobactrum coliformae* fermented glycerol. A few cultures were weakly urease positive in Christensen's medium but none in Rustigian and Stuart's, thus excluding their relationship to *Proteus*. Our cultures were all peritrichous when very young (5 hr. old) but they showed 'degenerate peritrichous' flagella when 18 hr. old.

Breed (personal communication) would include polar flagellate glucose-fermenting (aerogenic) but non-lactose fermenting organisms in the new genus *Aeromonas* Kluyver and Van Niel. The culture described by us as *Paracolobactrum coliformae* var. *marinum*[9] was found later to be monotrichous and would belong to *Aeromonas* but for the fact it is *MR*-positive. Flagellation is an important diagnostic characteristic in distinguishing the Paracolon-Aerobacter from *Aeromonas*. The failure of some coliform bacteriologists to determine the type of flagellation has led to misclassification of *Aeromonas* as *Paracolobactrum*, as emphasized by Breed. Sen and Dutt[10], describing a lactose anaerogenic but glucose aerogenic organism, identified it as *Aerobacter cloaceae*, though it should properly be classified as *Paracolobactrum aerogenoides* (or as *Aeromonas*, if flagellated at the poles). In view of the reported role of paracolons in the etiology of gastric infections, and that of *Aeromonas* in causing diseases of cold-blooded animals, more attention should be paid to their proper classification.

Detailed descriptions of the paracolon cultures will be published elsewhere. We thank Dr. Robert S. Breed for useful discussion and for a preprint of the section on the genus *Aeromonas* prepared for the 7th edition of "Bergey's Manual".

This communication is published by permission of the additional director of Industries and Commerce, Madras.

Availability to Dinitrofluorobenzene of some Amino Groups in Human Dentin and Ox Hide Collagen

HUMAN dentin (containing 80 per cent by weight of mineral material), ox hide collagen, and samples of dentin which were partially demineralized at 4° C. by soaking in either 1 *N* hydrochloric acid or 1 *N* trichloracetic acid, or 15 per cent versene (*p*H 7·3), were assayed for α- and ε-amino groups using Sanger's dinitrofluorobenzene method[1].

0·2 gm. of tissue was added to 0·5 gm. dinitrofluorobenzene (excess) in 66 per cent ethanol saturated with sodium bicarbonate and shaken for 36 hr. at room temperature. The dinitrophenyl protein thus formed was washed with water and ethanol, and hydrolysed for 16 hr. with 6 *N* hydrochloric acid in a sealed tube at 105° C. After extraction of the hydrolysate with peroxide-free ether, separation of the water-soluble ε-N dinitrophenyl lysine and ε-N dinitrophenyl hydroxylysine was achieved by means of paper-chromatography, using butanol/acetic acid/water (4 : 1 : 5) as solvent. The yellow spots were cut out, eluted into 5 ml. of 1 *N* hydrochloric acid, and their optical densities at 360μ recorded on the Beckman spectrophotometer.

Distinct differences between the availability of amino groups of dentin and those of similarly treated hide collagen were observed :

(1) Only 50–60 per cent of the total lysyl and hydroxylysyl ε-amino groups of hide collagen were available to the dinitrofluorobenzene[2], whereas in human dentin the availability of these amino groups increased linearly from 6 per cent in untreated dentin to more than 90 per cent in the fully demineralized dentin[3].

(ii) A linear increase (from zero to 10 micromoles/gm. protein) in the concentration of N-terminal amino groups during demineralization of dentin was observed. In accordance with other workers[2], no N-terminal amino groups were detected in hide collagen.

(iii) The molar ratio (*R*) of ε-N dinitrophenyl lysine to ε-N dinitrophenyl hydroxylysine, obtained from the dinitrophenylation of hide collagen, was almost theoretical (3·9)[4]; but in dentin collagen this ratio increased in a linear manner from 0·8 to 2·9 (theoretical maximum 3·7)[5], when plotted against the percentage dissolution of mineral material (Fig. 1). This implies that, especially in the early stages of the decalcification process, the availability to dinitrofluorobenzene of hydroxylysyl ε-amino groups exceeds that of the lysyl ε-amino groups, in spite of the much higher concentration of lysine residues. The same results were obtained using each of the abovementioned demineralizing solutions.

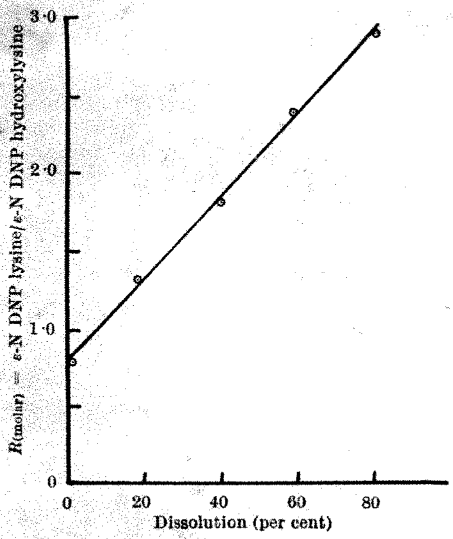

Fig. 1. Relative availability, to dinitrofluorobenzene, of lysyl and hydroxylysyl ε-amino groups of dentin collagen, during mineralization

Other workers[6] have suggested that polar side-chains of amino-acid residues in proteins and peptides may act as binding sites for ions ; and since the anionic binding power of the ε-amino groups of hydroxylysine is weaker than that of lysine[7], bound anions are expected to be liberated at a greater rate from hydroxylysyl than from lysyl amino groups, during demineralization.

It is therefore suggested that the ε-amino groups of lysine and hydroxylysine may play a part in the combination of mineral material with the protein matrix of human dentin.

Correlation between Deoxyribonucleic Acid Content and Volume of Individual Nuclei in Different Tissues of the Rat

IT has been shown that in the liver[1], and in several other organs[2], of the rat the nuclear classes determined according to the deoxyribonucleic acid content correspond to the nuclear volume classes. An objective analysis was performed in order to see if in the individual nuclei of a given organ a correlation exists between deoxyribonucleic acid content and volume. The results of measurements obtained with E. Pisi[2] were used in this study. The relative deoxyribonucleic acid content of the individual nuclei was obtained by means of the histophotometrical method of L. Lison[3]. The great majority of the nuclei being practically spherical in shape, the nuclear volume was calculated by a simple geometrical formula from the projection surface.

Fig. 1 summarizes the results obtained for the thyroid gland for two rats (105 and 106). The regression lines and the correlation coefficients *r* (0·816 and 0·536) show that, if the degree of correlation can be varying in the same organ from one individual to another, in each case a real linear correlation exists between the deoxyribonucleic acid content of the different nuclei and their volume.

Similar results were obtained for other organs, which like the thyroid gland contain practically only one nuclear class (kidney, endocrine pancreas). In organs with different nuclear classes (liver, exocrine pancreas) conditions seem to be more complicated ; they will be the subject of a further study.

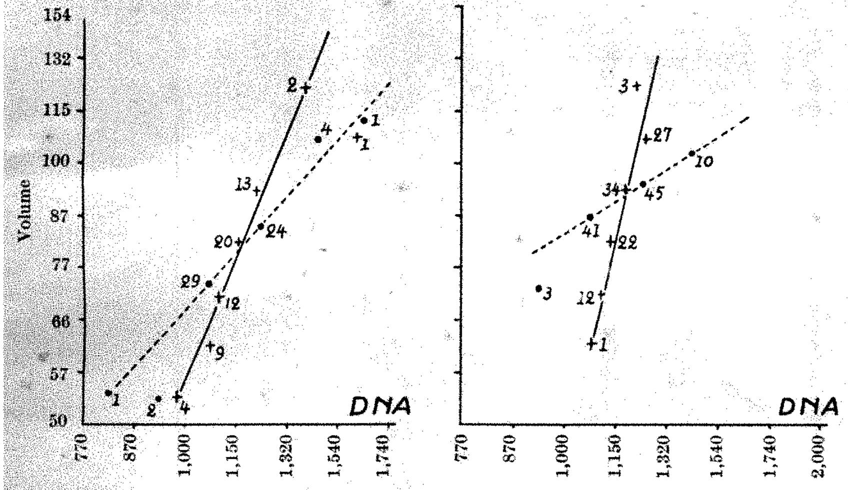

Fig. 1. Correlation between deoxyribonucleic acid content and nuclear volume in the thyroid gland of the rats 105 and 106: regression lines. Left: Thyroid gland of rat 105; *r*, 0·816; *n*, 61. Right: Thyroid gland of rat 106; *r*, 0·536; *n*, 99. *n*, number of measurements (the number of measurements from which the corresponding mean value was calculated are indicated next to each point); *r* = correlation coefficient

These investigations were carried out with a grant from the Fonds National de la Recherche Scientifique.

Human Fœtal Ventricular Outputs

In a comprehensive study of the fœtal circulation in the lamb, G. S. Dawes, Joan C. Mott and J. G. Widdicombe[1] showed that in the fœtus the left ventricular output exceeded that of the right ventricle. In a study of the ventricles of the post-natal human heart[2], I showed, by observations of the weight of the ventricular mass and of its parts, that right ventricular atrophy is the normal event in the period immediately following birth, and that the weight ratio between right and left ventricles which is characteristic of adult hearts is normally found from the age of six months onwards. Additional unpublished observations on the thickness of the ventricular walls during the period of right ventricular atrophy suggest that in the human fœtus, as in the lamb, the output of the left ventricle exceeds that of the right. As experimental observations of the type performed on the fœtal lamb are unlikely to be made on a human fœtus, these observations may be of some interest.

The measurement of the thickness of the ventricular walls is unsatisfactory both in theory and in practice. One big difficulty is that of making observations at strictly comparable points on the ventricular walls of different hearts. For this and other reasons, I originally determined to rely only on observations of the weight of the myocardium in the survey quoted above. However, when it became obvious that right ventricular atrophy was a normal post-natal event, I began to measure the thickness of the ventricular walls in order to compare changes in such measurements with the changes in weight. In order to obtain reasonably comparable observations, the measurements were made with flat-bladed callipers reading to 1/10 mm. at five points. These were: (*a*) anterior wall of the infundibulum, and (*b*) across the infundibulo-ventricular crest (crista supraventricularis). In both these measurements one blade of the callipers was inserted through the pulmonary orifice of the right ventricle, parallel to the interventricular sulcus in the first, and parallel to the atrioventricular sulcus in the second. (*c*) The posterior wall of the right ventricle—calliper inserted into the tricuspid orifice posteriorly and directed parallel to the interventricular sulcus on the inferior surface of the heart. (*d*) The lateral wall of the left ventricle, between the anterior and posterior groups of papillary muscles. (*e*) The thickest part of the septum.

In each of these measurements the callipers included the trabeculæ and avoided the bases of the papillary muscles. The measurements were made on specimens which had been fixed in 10 per cent formol-saline for 2–3 days.

In practice the septal and left ventricular wall measurements always resembled each other closely. For this reason only the measurements of the free wall of the left ventricle are quoted. Table 1 gives a summary of the findings at four age periods.

Table 1. MEAN THICKNESS OF VENTRICULAR WALLS IN MM.

Age period	No. of specimens	Right ventricle (*a*)	(*b*)	(*c*)	Left ventricle (*d*)
Full term	19	4·2	6·1	4·1	5·2
4–6 months	12	2·5	3·8	2·9	8·0
Second year	8	2·9	4·4	3·0	9·0
Sixth year	4	3·8	6·1	3·9	10·4

The infundibulo-ventricular crest is always by far the thickest part of the right ventricular free wall, and in the fœtus is normally thicker than any part of the left ventricular wall or septum. The atrophy of the right ventricular wall in the early months is profound and is not made up, in thickness, until six years have passed. In contrast the left ventricular free wall and septum grow rapidly in thickness from the beginning.

An estimate of the surface area of either ventricular free wall may be obtained by setting its weight (used as a measure of the volume of the myocardium) against its thickness. In the case of the right ventricle, the weight of its free wall in gm. was divided by its thickness, measured across the infundibulo-ventricular crest, in mm., and for the left ventricle the weight of its free wall divided by its thickness. The resultant figures are arbitrary, and are only used for comparing one heart with another, or one group of hearts with another. These two calculations were made for each specimen, and taking the first two age groups summarized above, give mean estimates of surface area as shown in Table 2.

Table 2. Mean Estimate of Surface Area of Free Wall

Age period	No. of specimens	Right ventricle	Left ventricle
Full term	19	1·0	1·5
4–6 months	12	1·5	1·9

In an irregular cavity such as a cardiac ventricle, surface area will be related to volume in roughly the same way as in a sphere, where volume increases as the cube of the radius, and surface area as its square. Therefore, changes in surface area may be made to indicate changes in volume by raising them to the power of 3/2. Thus the increase in the volume of the right ventricle in the period chosen would be indicated by $(1\cdot5/1\cdot0)^{3/2} = 1\cdot8$, and that of the left ventricle by $(1\cdot9/1\cdot5)^{3/2} = 1\cdot4$.

This suggests greater increase in the capacity of the right than of the left ventricle in the period chosen. At the period 4–6 months an adult type of circulation with equal ventricular outputs is certain. The inference can thus be drawn that the functional capacity of the right ventricle before birth is less than that of the left ventricle. As the fœtal ventricles pump against the same peripheral resistance, a lesser capacity implies a lesser output. This conclusion is in accord with the belief that the general pattern of the circulation shown in the fœtal lamb is repeated in the human fœtus.

Delayed Implantation in the Grey Seal, *Halichoerus grypus* (Fab.)

Early in March 1870 a large grey seal cow was killed by Prof. W. Turner. "A large corpus luteum was in the left ovary but the uterus was empty[1]."

On January 3, 1956, we killed a grey seal cow on the Pembrokeshire coast. A moderate-sized corpus luteum, containing a central cavity, was found in the left ovary (Fig. 1). Externally the uterus showed no sign of pregnancy; but, in the left uterus, a blastocyst was found measuring 2·3 mm. by 1·8 mm., lying free in the lumen (Fig. 2). Its cells were virtually free of mitotic figures. The surrounding uterine epithelium and glands showed no evidence of impending implantation.

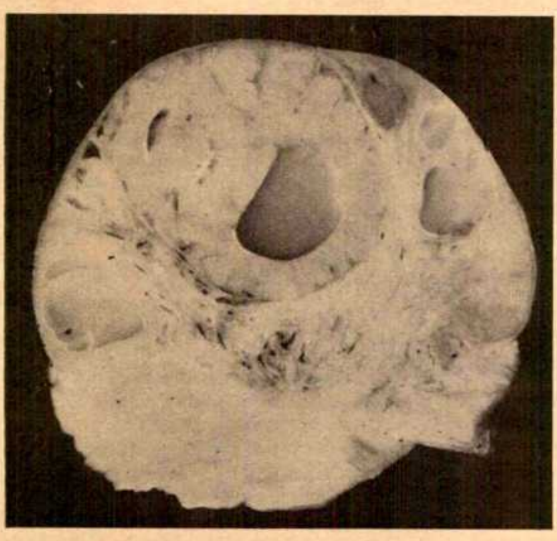

Fig. 1. Hand section of the left ovary, showing the corpus luteum with central cavity

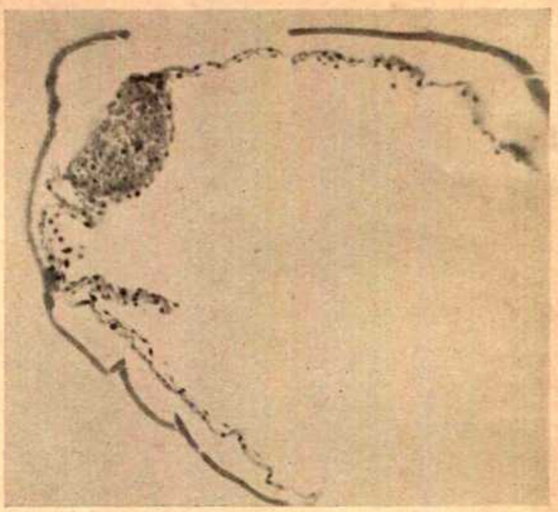

Fig. 2. Vertical section through the blastocyst, showing the zona (broken at one point), the trophoblast, primary endoderm and the inner cell mass

Three bulls all more than 90 in. in total length were shot at the same time. Two of these had the neck and shoulder development characteristic of sexually mature males. There were no sperm, however, in the testes or in the epididymes of any of the three bulls. Fertilization must therefore have taken place some time previously. Mating on the Pembrokeshire coast has been observed during September–October. Consequently delayed implantation seems apparent. Turner's original observation supports this conclusion.

Delayed implantation of the blastocyst has been previously recorded in two other Phocid seals; in the common or harbour seal by Fisher in 1954 [2] and in the elephant seal by Gibbney in 1953 [3].

A Culture Technique for *Venturia* spp. and a Turbidimetric Method for the Estimation of Comparative Sporulation

Growth and sporulation of *Venturia inaequalis* and *V. pirina* have been extensively studied in artificial culture. Miller[1] obtained objective measures of sporulation and also concluded that inoculum concentrations greater than 200,000 conidia per ml. had little effect on the final yield of conidia. Montgomery and Moore[2] grew cultures of *V. inaequalis* on sterilized apple twigs from which the bark had been removed. They obtained rapid growth and sporulation, and could remove most of the conidia easily without disintegration of the substrate, by shaking the cultures with water. In the following methods the advantages of a firm substrate have been coupled with the use of media of known or constant composition for studies of comparative sporulation under various nutritional conditions, and for the provision of routine supplies of conidia for fungicide bioassay.

The cultures are grown on filter paper cylinders standing in nutrient solutions. Whatman 541 filter paper is cut into rectangles of a size to produce, when rolled, cylinders of convenient length and diameter. These cylinders are then slipped into and held centrally by stainless steel rings. The dimensions I have used are 4·5 cm. × 3·5 cm. rectangles, rolled into cylinders 4·5 cm. long, and held by stainless steel rings as follows: outer diameter 5/16 in., thickness 1/64 in. and width 1/32 in. The cylinders are placed in 6 in. × ½ in. B.S.S. standard test-tubes and heat-sterilized before addition of nutrients. Culture media at pH 5·6 (for example, 10 per cent malt extract, as suggested by Miller[1]) are sterilized by filtration and 1-ml. aliquots are then dispensed aseptically into each tube.

Inoculum suspensions of conidia or mycelial fragments are prepared in sterile glass-distilled water. Each suspension is strained through fine organdie muslin into a 5 in. × ½ in. test-tube packed with cotton wool, inside a 6 in. × 1 in. boiling-tube. After filtration the muslin is removed and the plug of the outer tube replaced. Filtration is necessary owing to the otherwise inevitable blockage of pipettes, used for dispensing inoculum, by large mycelial fragments. Inoculum concentration is adjusted visually to an approximate turbidity of 0·1 (see below), which is equivalent to 2–300,000 conidia per ml. Each tube is inoculated with a volume of suspension calculated as sufficient just to cover the paper cylinders (0·2 ml. for the dimensions given above) and the tube is shaken and rotated to ensure even distribution. The cultures are incubated horizontally for 14–21 days at 18° C. They may be killed by the addition of two drops of formalin and stored at 5° C. to await estimation of sporulation.

Comparative sporulation is determined by turbidimetric estimation of suspensions produced from each culture, in order to avoid time-consuming counts of spore concentrations and the use of sampling methods. The following procedure has been adopted for the preparation and estimation of suspensions.

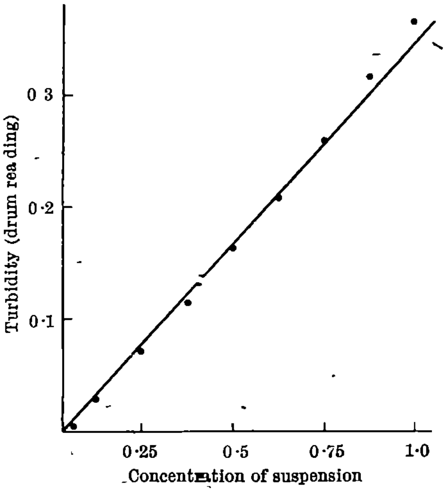

Fig. 1. Linear relationship between dilutions of a concentrated spore suspension and turbidity

Cultures of *V. inaequalis* are shaken vigorously for 1 min. with distilled water (6 ml.) and those of *V. pirina* gently for the same time. Vigorous shaking of the latter is undesirable as they produce comparatively few conidia, and the strongly segmented subaerial mycelium tends to disintegrate. Each spore suspension is strained through one thickness of fine organdie muslin into a 6 in. × 1 in. boiling-tube. The process is repeated with a further 6 ml. of distilled water and gentle shaking. This treatment yields 10–12 ml. of suspension, containing 95–99 per cent of the conidia and a few small fragments of mycelium. Each suspension is centrifuged at 2,000 rev./min. and the supernatant liquid replaced by distilled water; this is repeated until no trace of colour remains in the liquid, in order to avoid interference with the turbidimetric estimation. The final spore deposit is resuspended in either 1 ml. or 10 ml. of distilled water, depending on its magnitude, and the suspension stored at 5° C. in the presence of formalin, to prevent microbial deterioration.

The turbidity of each suspension is recorded using a Hilger photoelectric absorptiometer (Spekker) with neutral filters and cells of 1 cm. path-length, micro-cells being used for the 1-ml. suspensions. An examination of the relationship between dilutions of a concentrated spore suspension and turbidity showed it to be almost linear over the range of drum readings 0·02–0·3; but beyond this range there was an increasing departure from linearity (Fig. 1). Concentrated 10-ml. suspensions are therefore adjusted by dilution to give readings in the 0·02–0·3 range and the necessary corrections applied to give directly comparable estimates of spore production by the cultures. Readings below 0·02 cannot be accurately determined, and 1-ml. suspensions are therefore prepared, the observed drum readings being divided by 10 to obtain results comparable with those of the 10-ml. suspensions. All results are expressed as comparable turbidities.

Results obtained by the use of these methods have been briefly reported by Kirkham[3], and Kirkham and Flood[4], and will be described in detail elsewhere.

Intake of Streptomycin by Peach Leaves

Previous work[1] has shown that streptomycin sulphate, when applied as an aqueous spray to foliage, prevented the development of blast of stone fruit, caused by *Pseudomonas syringae* van Hall. Mitchell *et al.*[2] found that streptomycin was taken in and translocated upwards to the leaves when applied in a lanolin paste to bean plant stems. As part of a programme designed to gain knowledge of the movement of streptomycin in peach trees (*Prunus persica* (L) Batsch), investigations were carried out to determine whether streptomycin can be taken in through uninjured leaf surfaces and become systemic.

In one series of experiments, seedlings (var. Golden Queen) grown in pots in a glasshouse were sprayed with aqueous solutions of streptomycin sulphate and, after varying intervals, were washed by immersing the foliage in running water for four minutes, to remove surface streptomycin. The presence of antibacterial activity subsequent to washing was determined by inoculating the plants with *Ps. syringae*. All plants in an experiment were inoculated on the same occasion. The percentage infection obtained when a concentration of 100 μgm./ml. streptomycin base was used is given in Table 1. Plants were dry approximately one hour after spraying.

Table 1. *Ps. syringae* INFECTION OF PEACH LEAVES WHEN WASHED AT INTERVALS AFTER SPRAYING WITH 100 μGM./ML. STREPTOMYCIN

	Time after treatment before plants were washed				Differences for significance at 1 per cent
	Check	15 min.	2 hr.	3 days	
Per cent leaf infection*	100	97	89	65	
Equivalent angle	90	84	75	54	21
Mean lesion diameter (mm.)	10·7	11·6	9·5	7·3	3·2

* Number of lesions out of 20 inoculation points on each of five plants.

Since a time-interval between spraying and washing was required before infection was significantly reduced, it would seem that washing removed surface streptomycin; and that the significant reduction in infection with plants washed three days after spraying was due to streptomycin retained by the leaves. This experiment has been repeated with substantially the same results. Similar results were obtained when leaf tissue extracts from similarly treated plants were assayed by the paper-disk plate method, using *Bacillus subtilus* A.T.C.C. 6633 as test organism. The only extracts which inhibited the test organism were from plants washed three days after spraying.

More conclusive evidence that streptomycin was taken into leaf tissues was obtained by painting solutions containing 1,000 μgm./ml. streptomycin on the under surfaces of leaves for three consecutive days, followed by washing the plants and inoculating upper leaf surfaces. In one such experiment, 11 lesions developed on treated leaves and 71 on untreated leaves.

Preliminary investigations indicate that the time required for streptomycin sulphate to enter leaves in effective or measurable quantities is influenced by the climatic conditions; for example, the period was reduced when treated plants were held at high (> 90 per cent) relative humidity.

When aqueous solutions of streptomycin sulphate containing up to 1,000 μgm./ml. streptomycin base were painted on proximal or distal half leaves, and plants placed in an atmosphere of greater than 90 per cent relative humidity, no antibacterial activity was detected in untreated areas by either bioassay or plant infection techniques. Activity was detected, however, in treated and washed half-leaves of the same plants. No indications of streptomycin translocation were obtained when a colloidal streptomycin formulation with high lipoid solubility properties was painted on half leaves or sprayed on half plants.

When whole peach leaves, except for the petioles, were placed in aqueous solutions of streptomycin, no reduction in streptomycin concentration was detected by bioassay, but when macerated peach leaf tissue was added to streptomycin solutions, the amount of activity detected in the supernatant liquid was considerably reduced[3]. The reduction was not due entirely to dilution or to a change in *p*H.

Charles[4] suggested that xylem elements may be negatively charged and therefore interfere with translocation of positively charged streptomycin molecules.

The work outlined above indicates that streptomycin can enter peach leaves following foliar applications, but no evidence can be found that it becomes truly systemic when applied to leaves. These findings are not inconsistent with the view that streptomycin may become bound in leaf tissues in some way following foliar sprays.

I am grateful to Dr. H. R. Thompson for statistical analyses and to Glaxo Laboratories, England, for supplying the colloidal streptomycin formulation.

Effects of Temperature and Length of Day on the Sex Expression of Monoecious and Dioecious Angiosperms

IT has been demonstrated[1] that production of female flowers in *Cucurbita pepo* is delayed when plants are grown in high temperatures and during long photoperiods. Previous investigations indicated a similar effect of temperature and length of day on the sex of *Ambrosia*[2].

In natural summer conditions monoecious plants of *Mercurialis ambigua* L. fil. produce one female flower and a cluster of male flowers in each leaf axil. Ten plants were grown in 24-hr. photoperiods and thirteen in 8-hr. photoperiods throughout their lives at day temperatures of 26°–32° C. and night temperatures of 17°–21° C. All plants produced male flowers from the second foliar node upwards; but long days significantly delayed the production of female flowers. The average degree of femaleness attained at each node in each group of plants, as a percentage of the maximum possible, is given in Table 1. 100 per cent of femaleness at a node is reached when all plants of the group have two female flowers at that node.

In a second experiment, plants were grown in continuous light (8 hr. natural daylight supplemented by 16 hr. light at 500 ft. candles from a mercury lamp). Twelve of these plants were grown at a constant temperature of 24° C. and another twelve at 15·5° C.

Table 1. AVERAGE PERCENTAGE OF FEMALENESS

Day-length	Node numbers			
	2	3	4	5
8 hr.	3·8	61·5	92·5	100
24 hr.	0·0	15·0	35·0	80

Table 2

Temperature	Node number 2	3	4	5	6	7	8	9
24° C.	4·5	13·7	27·5	32·0	41·0	50·0	54·5	54·5
15·5° C.	67	100	100	100	100	100	100	100

All produced male flowers at each node; but development of female flowers was strongly delayed at the higher temperature. Percentage femaleness, shown in Table 2, was determined as in the previous experiment.

Female plants of *Cannabis sativa* L. are known to produce male flowers under certain conditions[3]. My investigations indicate that environmental conditions affecting the sex of monoecious *Cucurbita* and *Mercurialis* affect female hemp similarly. Female plants can be induced to grow through a male phase before reaching their normal female expression.

When plants were grown in continuous light for 45 days at a day temperature of 21°–26° C. and a night temperature of 15·5°–21° C. and then transferred to 8-hr. photoperiods at the same temperature, male flowers were produced at the lowest flowering node (node 7 or 8) of the female plants.

These results are particularly interesting as they indicate the possibility that growth of female as well as monoecious plants through a male phase before they produce female flowers is a general phenomenon. Female plants normally reach the female phase before flowers develop and usually produce no male flowers, but by artificially delaying the attainment of femaleness, male flowers are produced.

The work is supported by a grant from the Agricultural Research Council, and experimental facilities have been supplied by the Nuffield Foundation.

Soil Transmission of Scottish Raspberry Leaf-Curl Disease

LEAF-CURL is the most important virus disease occurring in the raspberry-growing districts of eastern Scotland, where it has been known for many years[1]. It seems to be caused by raspberry ringspot virus, which can be transmitted by mechanical inoculation from raspberry plants with leaf-curl disease to plants of *Chenopodium amaranticolor* Coste and Reyn. and several other species[2]. None of the many kinds of arthropods tested as possible vectors transmitted the virus[2], and it seemed likely that the virus might be soil-borne.

In May 1955, soil was collected from the site of a recent severe outbreak of raspberry leaf-curl, potted and kept in a heated, insect-free glasshouse. Raspberry root-cuttings of the variety Malling Jewel were planted in the pots and also in pots containing the steam-sterilized potting mixture (John Innes potting compost No. 2) usually used. No symptoms of virus infection were observed in 1955; but in April 1956 fifteen out of thirty-two plants growing in soil from the leaf-curl site showed symptoms of leaf-curl. Local lesions were produced in leaves of *Chenopodium amaranticolor* inoculated with sap extracted from the leaves of each raspberry plant with symptoms: the *C. amaranticolor* plants were not infected systemically. Plants grown from root cuttings in sterilized potting mixture showed no symptoms of leaf-curl, and sap from them produced no lesions in leaves of *C. amaranticolor*.

It is also interesting that soil collected from the site of this particular leaf-curl outbreak harbours at least two other viruses. A virus of the tobacco-necrosis type was isolated from the first roots that grew on Malling Jewel root-cuttings planted in soil from the leaf-curl site: three out of eight plants contained the virus. No virus was detected in the roots of control plants grown in sterilized potting mixture. The virus resembled the tobacco necrosis viruses in producing large, discrete, necrotic lesions in the inoculated leaves of French bean variety Prince, in infecting plants of many other species without becoming systemic and in having a thermal inactivation point of between 90° and 95° C. when heated for ten minutes. No previous record is known of a virus of this type in raspberry.

Cadman[2] showed that sugar-beet seedlings became infected with a virus of the ringspot type when grown in potted soil from this leaf-curl site. I have repeatedly confirmed this finding by inoculating sap from macerated seedlings on leaves of *C. amaranticolor*, which develops local lesions and systemic symptoms when infected with this virus. Most of the infected seedlings were symptomless, and the virus appeared to be present more often in the roots than in the shoots of seedlings and never in the shoot only. No virus was isolated from sugar beet grown in sterilized potting mixture. Cross-protection tests in *Nicotiana tabacum* var. White Burley and in *Petunia nana* failed to show any relationship of the virus from sugar beet to raspberry ringspot virus. Its properties will be described elsewhere. Soils which, like the one used in these experiments, harbour three distinct plant viruses may be exceptional; but it seems more likely that soil-borne viruses are much commoner than has hitherto been suspected.

Raspberry ringspot virus and the ringspot virus from sugar beet both seem to resemble viruses of the tobacco-ringspot group. Many viruses of this type have been described, and they cause numerous diseases of economic importance: none is known to be transmitted by an arthropod vector from plants not infected by another virus, although it has been suggested that tobacco ringspot virus is transmitted by the aphid *Myzus persicae* from *Gladiolus* plants also infected with yellow bean mosaic virus to healthy *Gladiolus*[3]. The results described above now suggest that viruses of the tobacco-r[illegible] type may commonly be transmitted thro[illegible]

FORTHCOMING EVENTS

Monday, September 10—Saturday, September 15

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH (at Government Offices, Horseguards Avenue, London, S.W.1)—Third International Congress on "High Speed Photography".

Thursday, September 13

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. A. D Hibberd: "Recent Developments in Titanium Oxide Pigments".

Thursday, September 13—Monday, September 17

TEXTILE INSTITUTE (in the Congress House, Zurich, Switzerland)—Conference on "Static Electricity in Textiles".

Friday, September 14—Saturday, September 15

BIOCHEMICAL SOCIETY (on Friday in the Department of Biochemistry and Pharmacology, University College, Dublin, and on Saturday in the Department of Biochemistry, Trinity College, Dublin), at 10.30 a.m.—Scientific Papers.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LABORATORY MANAGER (with recognized engineering apprenticeship, and corporate membership of a senior professional Institution or equivalent qualifications, and broad experience in electrical and mechanical engineering)—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting Ref. 550/2 (September 17).

MATHEMATICAL PHYSICIST (with an honours degree and research or industrial experience) IN THE RESEARCH LABORATORIES, Central Electricity Authority, Leatherhead, to carry out work with a mathematical background in applied physics, such as flame radiation, stress analysis, fluid flow or temperature turbulence, and to assist colleagues with the mathematical side of their work—Director of Establishments, Central Electricity Authority, Winsley Street, London, W 1, quoting N/644 (September 17)

CHEMIST (with a university degree, or equivalent qualification, in chemistry, preferably with training in physics or geology, willing to spend periods of up to six months in the field on soil surveys) IN THE DEPARTMENT OF RESEARCH AND SPECIALIST SERVICES, Federation of Rhodesia and Nyasaland Ministry of Agriculture, for duties including routine and research work on soil fertility and on all related agricultural products and problems—Public Service Attaché, Rhodesia House, 429 Strand, London, W.C.2 (September 22).

RESEARCH ASSISTANT (with an honours degree in biochemistry or pharmacology) to work on the biochemistry of hypoglycæmic sulphonamides—Department of Pharmacology and Therapeutics, Queen's College, Dundee (September 22).

SCIENTIFIC OFFICER (with a university degree in agriculture or agricultural botany and a sound knowledge of the principles of genetics and practical plant breeding, preferably with experience in the inspection and certification of seed potatoes) IN THE PLANT BREEDING DIVISION, Ministry of Agriculture, Loughall, Co. Armagh, for work on potato breeding—The Secretary, Civil Service Commission, Stormont, Belfast, N. Ireland (September 24).

SCIENTISTS (with good honours degrees in physics, engineering, mathematics or a relevant social science, with ability to handle data and preferably with experience in industry or operational research) FOR THE SCIENTIFIC DEPARTMENT, Field Investigation Group, London Headquarters, National Coal Board, to assist in teams studying production and human problems in the coal industry—National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting SS/379 (September 24).

SENIOR LECTURER IN PATHOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 24).

LECTURER IN BACTERIOLOGY—The Secretary of University Court, University, Glasgow (September 28).

ORGANIC CHEMIST [illegible] BIOCHEMIST (preferably with experience), to undertake synt [illegible] ioactive compounds for metabolic investigations at th [illegible] d Research Station, Institute of Cancer Researc [illegible] ital, Chalfont St Giles—The Secretary, Chest [illegible] ute, Fulham Road, London, S.W.3, qu [illegible]

PHYSICAL CHEMIST or BIOCHEMIST for investigations on nucleo proteins and other biological substances—The Secretary, Cheste Beatty Research Institute, Fulham Road, London, S.W.3, quotin "J.A.V.B." (October 1).

SENIOR LECTURER or LECTURER IN PHYSICAL CHEMISTRY o INORGANIC CHEMISTRY at the University of Melbourne—The Secretary Association of Universities of the British Commonwealth, 36 Gordo Square, London, W.C.1 (Australia, October 12).

LECTURER IN SOCIOLOGY and a LECTURER IN BOTANY at the University of Natal—The Secretary, Association of Universities of the Britis Commonwealth, 36 Gordon Square, London, W.C.1 (October 15).

FELLOW (chemist, with experience in radiochemical techniques IN THE DEPARTMENT OF RADIOCHEMISTRY, Research School of Physica Sciences, Australian National University, Canberra—The Secretary Association of Universities of the British Commonwealth, 36 Gordo Square, London, W.C.1 (Australia, October 29).

LECTURER (with a university degree in electrical engineering preferably with experience in heavy electrical engineering and prepared to teach in this branch) IN ELECTRICAL ENGINEERING at the University of the Witwatersrand, Johannesburg—The Secretary Association of Universities of the British Commonwealth, 36 Gordo Square, London, W.C 1 (October 31).

DIRECTOR OF THE UNIVERSITY OF LONDON COMPUTATIONAL UNIT —The Secretary to the Senate, University of London, Senate House London, W C.1 (November 15).

AGRONOMIST (with a good honours degree and preferably with some practical experience) at the Gambia Rice Farm, to undertake experiments in the cultivation of irrigated rice and of alternative crops suitable for dry season cultivation under irrigation—The Director o Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/12/08

ASSISTANT EXPERIMENTAL OFFICER (with a knowledge of biochemistry or chemistry) to assist in metabolism studies in the Director's laboratory—The Secretary, Rowett Research Institute, Bucksburn Aberdeenshire.

ASSISTANT REGIONAL TRIALS OFFICER (graduate in agriculture o botany, preferably with practical experience in crop production) a Norfolk Agricultural Station, Sprowston—The Secretary, Nationa Institute of Agricultural Botany, Huntingdon Road, Cambridge.

CHEMIST (with at least five years research experience in some field of polymer chemistry), to lead a team to carry out a basic study of the mechanism, kinetics and properties of linear type polymers—The Director, Inveresk Gate, Musselburgh, Midlothian, Scotland.

CHIEF ENGINEER (with a degree in civil engineering and at least five years experience in high level administration in the engineering field) IN THE DEPARTMENT OF HOUSING, Jamaica, to take charge of engineering section covering subdivision layouts and development, construction of houses, and workshop producing prefabricated components for houses—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.160/32/02/T.

GEOLOGISTS (2) (with first- or good second-class honours degree in geology, preferably with a background of mathematics and physics) IN THE GEOLOGICAL SURVEY DEPARTMENT, for water supply work and general geological survey—The Director of Geological Survey, P.O. Lobatsi, Bechuanaland Protectorate.

GRADUATE (with a good honours degree in economics, preferably with statistics as a subsidiary subject, with an interest in manufacturing industries and aptitude for mathematical methods) in a department concerned with operational research and the relations and interactions of technology and economics, for duties primarily in problems concerning costs but also to participate in the other work of the department—Dr. D. W. Hill, Director of Research, The British Cotton Industry Research Association, Shirley Institute, Manchester 20.

GRADUATE IN ZOOLOGY or PHYSIOLOGY, to work on the breeding and feeding of small laboratory animals, mainly mice—The Director, Laboratory Animals Bureau, M.R.C. Laboratories, Holly Hill, Hampstead, London, N.W 3.

MATHEMATICS GRADUATE (with good knowledge of higher mathematics) for programming work for an electronic computer—The City Treasurer, City Hall, Norwich.

PHYSICIST or ELECTRICAL ENGINEER, Scientific Officer grade (with a first- or second-class honours degree in physics or electrical engineering, or equivalent qualification, and preferably with some electronics experience), with the Ministry of Supply, R.A.E., Aberporth, for research and development on electronic instrumentation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.338/6A.

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (honours graduate, or equivalent, in chemistry or biochemistry), for research work on amino-acids in animal nutrition—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

LECTURES AND COURSES

NORTHERN POLYTECHNIC

HOLLOWAY, LONDON, N.7

Principal · A. S. M. Symons, Ph D., B Sc, A R C.S., D.I C., F.Inst.P

Day and evening courses for the internal and external B Sc degree examinations of the University of London in chemistry, physics, mathematics, botany, zoology and geology. Facilities for research in science (full-time and part-time) Courses for the M Sc. degree by written examination and dissertation in mathematics, physics and chemistry Day and evening courses for the Grad R I,C. and Grad Inst.P examinations Courses are also conducted (day and evening) for the intermediate examination of the Pharmaceutical Society, intermediate B Pharm. and first medical examinations of the University of London, and for the general certificate of education Next session begins September 24, 1956.

Prospectus on application Tel.: NORth 1686

CHELSEA POLYTECHNIC

DEPARTMENT OF PHYSICS

Session 1956-57 Postgraduate Evening Courses begin September 24, 1956 Available subjects. Acoustics, Nuclear Physics, Optics, Physical Principles of Electronics, Quantum Mechanics, Semiconductors, Theory of Electro-magnetism. Ancillary courses include Elementary Electronic Circuit Theory.

Enrolment · Tuesday, September 18, and Wednesday, September 19 6 to 8 p.m.

New students should make early written application to the Secretary, Physics Dept, Chelsea Polytechnic, Manresa Road, S.W.3, for further details.

IMPERIAL COLLEGE

CHEMICAL ENGINEERING DEPARTMENT

Course of ten lectures on "The Principles of Explosion Prevention and Control" by Dr. J H Burgoyne, Mondays at 2 30 p.m., commencing October 15, 1956.

Further details from Deputy Registrar, City and Guilds College, Exhibition Road, S W 7

CHELSEA POLYTECHNIC

(provisionally designated College of Advanced Technology)

COURSE FOR B SC. (SPECIAL) DEGREE IN PHYSICS

A course of four years duration suitable for students engaged in industry will begin on September 24, 1956. Students will attend two terms full-time and one term part-time each session and may register as internal students of the University of London

Application forms from the Principal, Chelsea Polytechnic, Manresa Road, S W.3.

UNIVERSITY OF BRISTOL

DIPLOMA IN PLANT PATHOLOGY AND PROTECTION

A postgraduate course leading to the above qualification will commence on October 1, 1956 The course is conducted in part at the Long Ashton Research Station, and includes opportunities for original investigation in any approved field of plant pathology (including entomology) or crop protection. It extends over a full session of three terms ending in June or July.

Honours graduates in botany, zoology, or chemistry, who wish to be considered for this course, should make early application to the Registrar, from whom full particulars may be obtained

SIR JOHN CASS COLLEGE

JEWRY STREET, LONDON, E C.3

Telephone No. ROYal 3383

The College prepares students by full-time, by part-time day and by evening courses in · Botany; Mathematics; Chemistry; Physics; Geology; Zoology, for the intermediate examination and the B Sc. general degree of the University of London for internal and external students and for the examinations of the Royal Institute of Chemistry, of the Institution of Metallurgists, and of the Institute of Physics. Full-time and part-time courses are also held for the B Sc. internal and external special degrees in chemistry, in mathematics and in physics, and for the B Sc. (Eng.) metallurgy degree. There are full-time courses for the London external special degrees in botany and in zoology. Facilities are provided for full-time and part-time research and postgraduate study and short courses of lectures are held on a variety of special topics

Applications for enrolment for the academic year 1956-57 may be made on forms to be obtained from the Secretary.

OFFICIAL APPOINTMENTS

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF EXTRA-MURAL STUDIES

Applications are invited for an appointment as Resident Staff Tutor. Applicants should have special qualifications in either (i) Physical Science or (ii) Industrial Studies (in which the tutor would be expected to develop work with industry in both trade union and management studies). The tutor's duties will be partly to organize extramural work in East Birmingham and partly to teach and develop work in his subject Salary in Grade II (£650 by £50 to £1,350 with efficiency bar at £900). Initial salary according to qualifications.

Applications (eight copies), together with names of two referees, should be sent by September 30, 1956, to the Director of Extra-Mural Studies, the University, Edmund Street, Birmingham, 3, from whom further particulars may be obtained

G. L. BARNES,
Secretary.

RITISH RAILWAYS RESEARCH DEPARTMENT

ssistant Librarian (female) required in British ways Research Laboratories at Derby, prebly under 25 years of age. Good general eduion, with G C E. English and French (or man), preferably at advanced level Library ociation First Professional Examination or d general experience in library routine. Typing ntial. Duties would include cataloguing, ining and preparation of material for Monthly tracts Review, compilation of bibliographies, general library duties such as preparation of erial for binding, stock-taking, checking loans, Salary £198 to £572 (according to age) lical examination Free and reduced rate elling facilities

pplications, stating age, qualifications, etc., to sent to Director of Research, British Trans- Commission (British Railways Division), 222 ylebone Road, London, N.W 1

RINCIPAL SCIENTIFIC OFFICER REed by the Atomic Weapons Research Establnent, Aldermaston, Berks, to conduct a promme of research into certain aspects of weapon gn. The work embraces a wide field of int but will be mainly electrical in character. licants should possess a first- or second-class ours degree in physics or electrical engineer- and have at least three years' postgraduate arch experience in one or more of the followfields. (a) Spark or arc discharge processes Generation of high energy high voltage pulses. Capacitor development. Salary: £1,390 to 80 per annum Contributory superannuation me. Married officers now living outside the blishment's transport area will be eligible for sing on one of the Authority's estates; alternly assistance towards legal expenses incurred ouse purchase may be payable.—Requests for ication forms, by postcard, to the Senior Retment Officer at the above address Please te ref A 1,000/34.

ANCHESTER REGIONAL HOSPITAL rd have a vacancy for a male or female Junior ntific Officer in the Blood Transfusion Service. honours degree in science, pharmacy or biology sential Duties will consist of technical work he Blood Transfusion Service Laboratories ry £525 by £25 to £628 during a probationary od normally of three years, then it is £650 by (3) by £35 (3) to £845—Applications, stating qualifications, previous experience (if any). the names of two referees, should be sent ediately to the Director, Blood Transfusion ice, Roby Street, Manchester, 1, from whom her particulars may be obtained.

OMPUTOR REQUIRED BY PNEUMOosis Field Research Unit of N C B 's Scientific t, in London G.C E with mathematics at " level, or equivalent required. Appointment erannuable), according to qualifications and rience, within inclusive scales as either Scien- Technical Officer 3 (£472 to £642 male, £428 572 female) or Scientific Technical Officer 4 1s 6d at age 15, rising to £9 19s 7d male, emale at age 27)—Write, with full particulars ge, education, qualifications and experience, National Coal Board, Staff Dept, Hobart se, London, S W.1, marking envelope SS/385, re September 17, 1956.

INISTRY OF AGRICULTURE, FISHERIES Food require temporary Assistant Technical cers at London and Kendal. Duties concerned (i) production and distribution of agricul- l lime, (ii) fertilizer subsidy. Travelling ined Qualifications: degree in agriculture, at least 21 Starting pay £621 (London) (provincial) if 25 or over; less below age Maximum £918 (London) £878 (provincial) r for women—Forms from Ministry of our and National Service, Technical and ntific Register (K), 26 King Street, London, 1, quoting G.301/6A

IENTISTS REQUIRED BY NATIONAL Board's Field Investigation Group of Scien- Department at London Headquarters, to assist eams studying Production and Human prob- in the Coal Industry Good honours degree physics, engineering, mathematics, or a rele- social science is required, with ability to dle data, experience of industry or operational arch an advantage. Appointments (super- able) according to qualifications and experi- , within inclusive scales, as either Scientist 2 to £1,290 male, or Scientist 3, £617 to £1,125 —Write, with full particulars of age, eduon, qualifications and experience, to National Board, Staff Department, Hobart House, don, S W 1, marking envelope SS/379, before tember 24, 1956 For those interested, innal interviews can be arranged to discuss the with senior members of the staff.

WOOLWICH POLYTECHNIC

LONDON, S E 18
PRINCIPAL. J. S. TAIT, Ph D, B Sc., A R T C., M I.E E., M I Mech.E

Applications invited for: (i) Senior Lecturer in Organic Chemistry—high academic and research qualifications are essential, facilities for research available (ii) Lecturer in Inorganic and Physical Chemistry—candidates should be able to teach their branch of Chemistry to Special (Honours) Degree standard, facilities for research available The proposed salary scales are: Senior Lecturer, £1,350 by £30 to £1,550; Lecturer, £1,200 by £30 to £1,350; plus London Allowance of £36 to £48

Particulars and application form from Clerk to Governors, to be returned by September 21, 1956

UNIVERSITY OF LEEDS

DEPARTMENT OF LEATHER INDUSTRIES

Applications are invited for appointment as Lecturer in the Department of Leather Industries at a salary on the scale £650 by £50 to £1,350 a year, according to qualifications and experience Candidates should be graduates in chemistry with a knowledge of modern synthetic resins and rubbers and the person appointed will be required to give instruction in and to investigate the application of these to various leathers.

Applications (three copies) stating date of birth, qualifications and experience, together with the names of three referees, should reach the Registrar, The University, Leeds, 2 (from whom further particulars may be obtained) not later than October 15, 1956

WESTERN AUSTRALIAN MUSEUM AND ART GALLERY

DIRECTOR OF THE MUSEUM

Applications are invited for appointment as Director of the Western Australian Museum The salary range is £A 2,400 to £A 3,000 per annum with superannuation similar to the F S S.U. or under the State superannuation and family benefits act if that can be arranged Commencing salary will depend on qualifications and experience. Conditions of appointment may be obtained on application to the Agent General for Western Australia, Savoy House, London, or Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1.

Applications should be addressed as follows Hon Mr. Justice Wolff, President, Museum and Art Gallery of W A., c/o The Supreme Court, Perth, Western Australia. The closing date for applications is November 30, 1956

A. A WOLFF,
President

UNIVERSITY OF SHEFFIELD

Applications are invited for a post of Lecturer or Assistant Lecturer in Chemistry with special interests in general or inorganic or in physical chemistry. Salary scales: Lecturer £650 by £50 to £1,350. Assistant Lecturer, £550 by £50 to £650, with F.S S U and family allowance Initial salary according to qualifications and experience

Further particulars should be obtained from the Registrar, to whom applications (three copies), should be sent by September 29, 1956

UNIVERSITY OF SYDNEY

AUSTRALIA

Applications are invited for the position of Senior Lecturer in Aeronautical Engineering, to work in the field of Aerodynamics Salary will be in the range £A.1,800 by £A 70 to £A 2,150 per annum, plus cost of living adjustment (£A 52 men £A 39 women), and will be subject to deductions under the State Superannuation Act The commencing salary will be fixed according to the qualifications and experience of the successful applicant Finance available for home purchase to married male members of staff.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1. The closing date for the receipt of applications in Australia and London is October 8, 1956

UNIVERSITY OF LIVERPOOL

Applications are invited for appointment to the post of Lecturer in the Department of Applied Mathematics, at an initial salary within the range £650 to £1,000 per annum, according to qualifications and experience.

Applications, stating age, academic qualifications and experience, together with the names of two referees, should be received not later than September 20, 1956, by the undersigned, from whom further particulars of appointment may be obtained.

STANLEY DUMBELL
Registrar

BIRKENHEAD EDUCATION COMMITTEE

BIRKENHEAD TECHNICAL COLLEGE

Principal: C V. Vinten Fenton, M Sc., A M I Mech E., A M.I.E E

Applications are invited for the following appointments Science Department, Three Assistants Grade B (for physics, general chemistry, mathematics). Salaries in accordance with the Burnham Technical Report

Further particulars and forms of application may be obtained from the undersigned, to whom completed applications should be returned by September 22, 1956.

H. GLYN WILKINSON,
Director of Education.

63 Hamilton Square,
Birkenhead.

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MEDICAL BIOCHEMISTRY AND PHARMACOLOGY

Applications are invited from science graduates for a research appointment (financed by the Colonial Products Council) in the Department of Medical Biochemistry and Pharmacology Applicants should preferably hold the degree of Ph D, and will be required to undertake investigations on natural products of potential pharmacological interest The salary will be in the Grade II Lecturers' scale (£650 to £1,350) according to experience.

Applications should be sent by September 15, 1956, to Professor A C Frazer, Department of Medical Biochemistry and Pharmacology, the Medical School, Birmingham, 15

G. L BARNES,
Secretary.

The University,
Birmingham, 15

CHELSEA POLYTECHNIC

Grade B Assistant required for temporary post for one year in the Department of Physics, mainly for classes of G C E (Advanced level) standard Burnham scale, commencing rate according to age, qualifications and experience

Apply at once to Clerk to the Governors, Chelsea Polytechnic, Manresa Road, S W 3

D S.I.R REQUIRES AN ASSISTANT EXperimental Officer. Physical Chemist, at the Food Investigation, Low Temperature Research Station, Cambridge, to assist in studying the microbiology and chemistry of spoilage in eggs Qualifications: G C.E. Advanced level in Chemistry and Physics Over 22, pass degree or H N C in Chemistry generally expected. Salary £350 at age 18 to £755 (men) £350 to £675 (women) Equal pay scheme —Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting reference F 579 6A. Closing date September 22, 1956.

NATIONAL COAL BOARD INVITE APPLIcations for the following superannuable appointments on the London H Q Staff of the Director of Scientific Control, for Pneumoconiosis Field Research (a long-term investigation into the incidence of pneumoconiosis among mineworkers). Considerable travelling involved: salary according to qualifications and experience within inclusive scales stated Scientist (either Grade 2, £991 to £1,390 male, or Grade 3, £617 to £1,124 male) to set up and supervise a system, based on punched-card techniques, recording and analysing the location and movement of colliery workers, and undertaking relevant field investigations The analysis may involve the use of electronic computing Good honours degree, preferably in mathematics or statistics, required, but those taking final examinations this year will be considered Experience of punched cards desirable but not essential Ref. No SS/386 Scientific Technical Officer, Grade 2, to assist the Scientist (above) and to investigate and resolve queries connected with the routine maintenance of manpower records G C E. with at least one scientific subject at "A" level and preferably a higher qualification required, with an interest in statistical methods and techniques A knowledge of mining practices desirable but not essential (£603 to £639 male) Ref. No. SS/387—Write, with full particulars of age, education, qualifications and experience, to National Coal Board, Staff Dept, Hobart House, London, S.W 1, marking envelope with relevant reference number before September 28, 1956.

TECHNICIAN REQUIRED FOR DUTIES IN the Department of Applied Electrophysiology. Good knowledge of electronics with experience in the construction and maintenance of electronic apparatus Salary within the range £610 to £705 —Apply, in writing, to the Secretary, The National Hospitals for Nervous Diseases, Queen Square, London, W C 1

THE ROYAL SOCIETY

STOTHERT RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for a Stothert Research Fellowship in the field of Medicine, including the sciences on which medical knowledge is based. The Fellowship will be tenable in any hospital, medical school or other appropriate research institution or university department in the British Isles or at any other place approved by the Council of the Royal Society. Candidates, who must be of British nationality, should supply the usual personal details and give the names of two referees Testimonials will not be considered. Applicants and referees at a distance may write direct to the address given below, without first obtaining forms. The subject of the proposed research, and the place at which it would be carried out, together with the name of the Head of the Department, should be given. The appointment will be for two years in the first instance, from January 1, 1957, and may be renewed annually up to a total of four years. The stipend will be £800 per annum, with increments of £50 per annum, and superannuation benefits to which the successful candidate will be required to contribute 5 per cent of annual stipend and to which the Society will make a contribution of 10 per cent.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W 1, and should be received as early as possible and not later than October 1, 1956.

UNIVERSITY COLLEGE OF THE WEST INDIES

Applications are invited for (a) Lectureship and (b) Assistant Lectureship in Physics Salary scales (a) £900 by £50 to £1,200 by £50 to £1,600 per annum, (b) £750 by £50 to £850 per annum. Entry point determined by qualifications and experience Child allowance. F S S.U. Unfurnished accommodation, if available, at rent 5 per cent basic salary, or allowance in lieu. Passages paid for up to five persons on appointment, normal termination and study leave (once every three years)

Detailed applications (six copies), naming three referees, by September 29, 1956, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained

---

CHEMIST (BASIC GRADE) REQUIRED BY the Atomic Weapons Research Establishment, Aldermaston, Berks, for the control of chemical process and gas purification production plants in the Chemical Engineering Branch. Some of these plants are operated on a continuous basis and therefore shift work may be necessary. Candidates should possess A R.I.C., A M.I.Chem E. or have exempting qualifications; or alternatively hold an honours degree in chemistry or chemical engineering Some previous experience of plant control work is desirable but not essential. Salary £775 at age 25 to £1,060 at age 34 to £1,210 per annum Contributory superannuation scheme Married officers now living outside the establishment's transport area will be eligible for housing on one of the Authority's estates: alternatively assistance towards legal expenses incurred in house purchase may be available; until housed a lodging allowance may be payable. Requests for application forms by postcard to the Senior Recruitment Officer at the above address. Please quote ref. A 1159/34.

MEDICAL RESEARCH COUNCIL, GROUP for Epidemiological Research on Respiratory Diseases (Air Pollution) want honours graduate in science for research on the environmental aspects of air pollution in investigations which will be conducted from the University of Sheffield. Appointment will be for two years in the first instance. Salary within the range £600 to £900, according to experience Superannuation, Federated Superannuation System for Universities or National Health Service Superannuation Scheme. Child allowances. The successful candidate may be given honorary university status and will be permitted to devote some of his time to preparation of a Ph D. thesis —Apply (three copies), giving names of three professional referees, to Dr J. Pemberton, University of Sheffield, as soon as possible, from whom further particulars may be obtained.

BIOCHEMIST, BASIC GRADE, REQUIRED for the Biochemical Laboratory, The Queen Elizabeth Hospital, Birmingham, 15. Candidates must hold a University degree in science or the Associateship of the Royal Institute of Chemistry Salary according to Whitley Council Scales with allowances for postgraduate study or experience —Applications to be sent, as soon as possible, to House Governor, the Queen Elizabeth Hospital, Edgbaston, Birmingham.

(REPEATED ADVERTISEMENT)

UNIVERSITY OF ABERDEEN AND ROBERT GORDON'S COLLEGES

Applications are invited for the post of Reader in Applied Thermodynamics in the University and Head of the Department of Mechanical Engineering in Robert Gordon's Technical College Salary £2,000 per annum with superannuation (F S.S.U.) and children's allowance. Part of removal expenses refunded.

Applications (twenty copies), giving names of three referees, should be lodged not later than September 25, 1956, with the Secretary, The University, Aberdeen, from whom conditions of appointment and forms of application should be obtained.

DIRECTOR, BOTANICAL GARDENS, HOBART AND LECTURER IN BOTANY, UNIVERSITY OF TASMANIA

Applications are invited from graduates in Botany, Forestry or Agricultural Science for appointment either (i) Director of the Tasmanian Botanical Gardens, or (ii) the combined post of Director of the Tasmanian Botanical Gardens and part-time Lecturer in Botany in the University of Tasmania The salary for (i) will be in the £1,500 to £1,750 range, and for (ii) £1,750 to £2,150 range. Applicants for the combined position should possess qualifications in experimental botany and preference will be given to applicants with research experience in ecology Residence, Long Service leave, and superannuation benefits available.

Applicants may be offered appointment under (i) or (ii) according to qualifications Further particulars are obtainable from the Secretary to the Trustees, G P O. Box 676E, Hobart, Tasmania, with whom applications close on November 1, 1956. Applicants from the United Kingdom may obtain particulars from the Agent General for Tasmania, London.

B G OSBORNE,
Secretary

UNIVERSITY COLLEGE

IBADAN, NIGERIA

Applications are invited for Lectureship Grade II in Physiology. Revised salary scales: £1,000 by £100 to £1,300 per annum, or, for persons without registrable medical qualifications, £1,000 by £50 to £1,300 per annum. Entry according to qualifications and experience. Allowance up to three children £50 per annum per child resident in Nigeria, £100 per annum per child resident elsewhere Part furnished accommodation at rent up to 7 7 per cent of salary. Passages for appointee, wife and up to three children under 11 years on appointment, overseas leave and termination F.S S U Outfit allowance £60 Appointment three years initially.

Detailed applications (ten copies), naming three referees, by September 29, 1956, to Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, W C.1, from whom further particulars may be obtained

D.S I.R. REQUIRES CIVIL ENGINEERS, Ref. E 383/6A (Scientific Officer Grade) for hydraulic research, including work on models at the Hydraulics Research Station, Wallingford, Berks A Scientific Officer, Ref A 168/5A, is also required for mathematical analyses of hydraulic problems and related computational work. Qualifications: First- or second-class honours degree in appropriate subject or equivalent. Salary range: £565 to £995 (men), £565 to £912 (women) but equal pay scheme. Five-day week. Favourable housing prospects for married candidates.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting appropriate reference.

ASSISTANT PROFESSOR AT ROYAL Naval College, Greenwich The Civil Service Commissioners invite applications from men for this pensionable post, for appointment in April, 1957. Age at least 31 on July 1, 1956 Candidates must have a degree with at least second-class honours in chemistry and some teaching experience. The successful candidate will be required to teach the chemistry of fuels, explosives and plastics. Salary: £2,000 to £2,300 per annum. Exceptionally, starting pay above minimum Accommodation may be provided for an unmarried man Secondment from Scientific Civil Service would be considered —Further particulars and application form from Secretary, Civil Service Commission, 6 Burlington Gardens, London, W 1, quoting No 4620/56/7. Completed applications should be returned by September 21, 1956

EDUCATION FOR MANAGEMENT

IT is still less than ten years since the Urwick Committee issued its report on education for management and only nine since the British Institute or Management was established. In that period, owever, increasing attention has been given both o the selection of managers and administrators and o the training they should receive and where it is best given. Particular aspects of the broad problem have been discussed in connexion with the Civil Service and its reform, and following a report on ducation for management by one of the productivity eams which visited the United States in 1951, it has been discussed at conferences arranged by the Federation of British Industries and the universities of Great Britain as well as in connexion with the xpansion of university education in general and of technological education in particular. The Fleck Report on the coal industry in Britain emphasized he significance of leadership at the highest level or the efficient running of an industry, and also he importance of the coal industry, or any other industry, taking positive steps to throw up its own leaders, while Sir Eric James's little book "Education or Leadership" had already provoked a wider discussion on the implications of the post-war changes n the educational system of Britain.

There had thus been a good deal of discussion on the selection and training of managers before he recent public concern about automation had tressed the increasing importance of efficient management and the need for even greater care in the election and training of managers. At the annual general meeting of Unilever Ltd. on May 24, Lord Heyworth devoted a large part of his chairman's address to the importance of good management in industry, the qualities required in a manager to-day and the best means of finding and developing the necessary talent. Emphasizing that merit should be he only test of suitability for managerial rank, and hat no particular social or educational background s demanded, Lord Heyworth described briefly the methods of selection adopted by Unilever Ltd. For he scheme run in Great Britain, about half the uccessful candidates come from inside the firm, and of the external candidates most of them have had a university education; and Unilever's experience in he United Kingdom is that a degree in any field an form an adequate background and provide uitable mental training for the general side of business, though there are many posts for which a echnological education is essential.

Lord Heyworth remarks that the attitude of the universities to industry, as well as that of industry o the universities, is changing, and that the tradiional resistance to the employment of graduates is fast disappearing, while the universities are increasingly ready to co-operate with industry. He also aid that the most important training of the potential manager is done individually and on the job, and that it must be flexible and selective. There is no general scheme, and unless the right men are sent on the right courses, there can be a waste of time and even positive harm. For more senior managers the firm uses the opportunities provided by such institutions as the Administrative Staff College at Henley, and the advanced courses available at places such as the Harvard School of Business Administration, and he stressed the value of meeting in this way people from completely different fields of business, from the Civil Service and the nationalized industries. Industry, he remarked, should ensure that it sends students of high quality, and it can also help by seconding first-class men to assist on the instructional side; and if universities are to develop the teaching of business administration, he favoured the experiment of seconding the university teacher to industry for a year or two to gain an inside view of how industry works.

While the fullest use should be made of conferences and similar techniques for keeping a manager's mind supple and alert, it is also essential to delegate real responsibility. Special care, too, is necessary to avoid the dangers of inbreeding; but it is necessary to strike a mean, although more interchange between one business and another at senior levels has its merits in spite of practical difficulties. Unilever itself possesses an advantage in that the international diversity of its business enables it to widen the experience of many managers by postings to countries outside Britain. Such postings, and also promotions, are the work of 'placement committees', responsible for watching the progress of promising men and selecting and recommending the right man for the right vacancy. On the whole, this has proved the most satisfactory method; but methods of recruitment and selection and training require continuous examination.

Lord Heyworth's observations are the more interesting in the light of the report on "Management Succession" which was issued almost simultaneously by the Acton Society Trust*. In earlier reports the Acton Society Trust has already examined problems of training and promotion generally in nationalized industries. The present report is limited to the recruitment, selection, training and promotion of managers. It is not a manual of such methods, but represents the results of an examination of the policies and practices used for securing a succession of managers by more than fifty very large organizations, and attempts to set forth the lessons that can be learnt from their experience.

The general aim of the investigation, which was sponsored by the Joint Committee on Human Relations in Industry of the Department of Scientific Research and the Medical Research Council, and financed from Counterpart Funds derived from

---

* Management Succession: The Recruitment, Selection, Training and Promotion of Managers. Pp. vii+139. (London: Acton Society Trust, 1956.) 10*s*. 6*d*.

United States Economic Aid, was to gain knowledge which might assist management both in the larger and also in smaller companies, where many of the problems are similar. First, it analyses the educational background and careers of existing managers, and particularly attempts to discover what opportunities existed in the past for promotion from the shop floor. Next, it reviews the problems encountered in recruiting, selecting, training and promoting these managers and the methods used for solving them, while finally the attitude of employees to the promotion policies of a few selected companies are summarized.

This report accordingly is a contribution to the solution of one of the key questions in industry to-day—that of ensuring an adequate supply of managers of high calibre; and one of its most startling findings is that one-third of the very large companies the practices of which were studied are making no systematic efforts to secure such a succession. Of the 3,327 managers whose background was studied, more than half began as manual or clerical workers and went only to an elementary or an ordinary secondary school. One in five went to a public school, more than one in four to a grammar school and only one in five has a degree, and less than one in five a professional qualification. Nevertheless, the analysis of the background of the younger managers suggests that the successors to present managers will be better educated and more qualified and that, as might be expected from the wider educational opportunities, the proportion rising from the bottom will decrease.

It is the next two or three chapters that are of particular interest to the scientist. An analysis of the background of present managers with the view of discovering which factors are most advantageous from the point of view of promotion indicates that arts degrees, and especially when taken at Oxford or Cambridge, are far more advantageous than science degrees, and technical qualifications come well below a science degree. Non-technical professional qualifications appear to be more advantageous, however, ranking well above a science degree and even above an arts degree except one obtained at Oxford and Cambridge. Men from major public schools seem to have done well whether they possess a degree or not; but the results of this study raise the questions whether different criteria are applied in selecting arts graduates and graduates in science or applied science, and whether the latter class of graduates are given adequate chance to show if they have qualities justifying promotion to the highest managerial posts. It should be noted, however, that the staff of research departments were not included in the sample; and at the other end the disadvantage under which men holding the position of foreman suffer suggests the question whether they are given a fair chance of training and selection for promotion.

These are questions which demand consideration not only within industry but also in planning the expansion of technological education and to some extent the development of university courses, particularly postgraduate, since there is evidence that higher degrees in any university or faculty are much more advantageous than science degrees, though les so than first degrees in arts. The greater educationa opportunities and the higher standard required fo management have clearly made most companies look to the universities to supply more of their futur managers. It is true, as Lord Heyworth points out that training for management must be given largely within industry, even if industry does not requir the assistance of the universities and colleges o technology in giving such training; but the univer sities will be in a better position to supply industry with the type of graduate it desires if industry co-operates more closely and indicates clearly th qualities it is looking for in the graduates it seeks.

Conferences arranged by the Federation of British Industries have already done something in thi direction; but this study by the Acton Society Trus directs attention to one aspect of the present search for talent that is particularly serious in the existing man-power situation. Competition is intense for th more able recruits, and few companies can get all they wish; yet there are great differences in th wastage of graduates between different companies For graduates in science and applied science, these have varied in the past five years from 6 per cent to 63 per cent, and the average of 29 per cent for twelv companies is too high to be regarded with indifference For arts graduates the average is 32 per cent; and it appears that many companies have much to learn about the selection, introduction and training o graduates; they do not seem to be aware of the principle that scarce material must be used with forethought and economy.

The elimination of such preventable wastage i one means of reducing the shortage of talent; bu few companies have paid sufficient attention to locating talent and developing it in their own organ izations. The experience of companies which have paid considerable attention to this problem suggests that, in the absence of an active policy, many who are suitable for promotion will be overlooked. In a large organization it is impossible for the directorate to b aware of all its potential talent, nor is it safe to rely on the judgment of a man's immediate superior, even if he is made aware of his responsibility for looking for promising younger men.

The search for talent is neither easy nor withou difficulties, some of which appear very clearly in the chapter in this report which discusses the effect o promotion policies on staff generally. The exact method adopted is, however, less important than the way in which it is used and the spirit behind it and it is clear from this report that if British industry paid more attention to the subject, to the inequalities of opportunity which exist in different departments and to the problems of introducing and training graduates, and took more care with fundamenta training and planned experience which really broadened the individual through varied experience and intellectual stimulus, there might be less need to complain of shortage of talent. Ambitious young men, both during their initial training and even more when it is finished, and before they are given real responsibility, must inevitably feel frustration from time to time, and attempts to meet this difficulty would help to reduce the wastage and might well contribute to the elimination of some of the absurdities into which the present severe competition for talent has led recruitment. Moreover, there are the intangible factors, such as the climate of opinion.

The study shows beyond question that the shortage of good managers, particularly at the top, is both more noticeable and more noticed than in the past. This is due partly to the greater demands made on management by the need to make the best possible use of limited resources in a setting of full employment; partly to the growing complexity of management, which necessitates a high standard; and partly to greater specialization, which makes it more difficult to produce general managers and has restricted the number of people suitable for a particular job. Automation, which is scarcely mentioned in the report, has made it even less likely that the right kind of manager will turn up spontaneously when required, and may well have increased the importance of those scientific and technical qualifications which at present seem to rank low as qualifications for promotion. Unless, in fact, industry gives much more attention to the planning of management succession and to the identification and training of potential managers at an early age, the shortage of managers is likely to become even more acute, and with increasing educational opportunities such early selection will become more and more important; managers will be drawn increasingly from a more highly selected group than in the past—from rather more restricted backgrounds with higher educational qualifications.

There is no one answer to the problems of management succession and development; but what matters above all is the attitude of mind which is brought to bear upon them. If a firm is to attract and retain able people, it must be apparent that able employees can get on and will not be overlooked, that managers themselves recognize management development as an important part of their responsibilities and that unexpected as well as expected managerial vacancies can be filled without difficulty with really well-qualified people from within. This is only possible if management at the top makes it manifest that it is really aware of and interested in such problems, and seeks to foster the all-important favourable climate of opinion.

Nor is all this a matter of concern to industry alone. The recent discussions on the introduction of automation have shown how closely efficient management touches on social and economic welfare. It is not merely that all grades of management will need fuller knowledge of the technical factors that influence their decisions. Good management can do much to soften the impact of technological innovation on labour and even directly on society; and while the prime responsibility rests on industry, the education policy of Britain could well be shaped to increase the probability that industry's intake at all levels will be equipped as fully as possible to seize the opportunities which industry puts in the way of its personnel. Nor should it be forgotten that the nation's interests, as well as those of industry itself, demand vision and enterprise as well as technical competence in its leaders, and that educational and economic policy contribute largely to the formation of the conditions and climate of opinion which favour enterprise and imagination.

These are all factors to be heeded in considering the expansion of technological education, the universities' plans for the next quinquennium, and economic and social policy in general, as well as the measures industry—as individual units or in concert and in co-operation with the universities—could take to secure a reasonable succession of managers of the highest quality.

PEACEFUL USES OF ATOMIC ENERGY

Proceedings of the International Conference on the Peaceful Uses of Atomic Energy

Held in Geneva, 8 August–20 August, 1955. Vol. 8: Production Technology of the Materials Used for Nuclear Energy. Pp. ix+627. Vol. 9: Reactor Technology and Chemical Processing. Pp. x+771. (New York: United Nations; London: H.M. Stationery Office, 1956.) 10 dollars; 70*s*.; 43 Swiss francs each vol.

THESE are two volumes which must be read by all the chemists, physicists, and metallurgists working on nuclear reactors, for they contain a vast amount of information on the fissile and fertile fuels, on the moderators graphite and heavy water, and on the canning materials such as beryllium, zirconium, steels, and aluminium. Many of the articles are exhaustive treatises on special subjects.

The importance of Vol. 9 cannot be over-estimated; it reports the sessions devoted to the metallurgy of thorium, uranium and plutonium, the fabrication of fuel elements, such as the stainless-steel liquid-metal bonded slugs used in the sodium-graphite and breeder reactors, and the dispersion-type elements as used in the materials testing reactor and in the 'swimming-pool' reactors. The use of liquid metals, and the corrosion they cause, is extensively reported almost for the first time, the chemical processing of irradiated fuels occupies a score of papers, and finally the storage and disposal of wastes are reported. The review of wastes with which the volume opens ought to have been grouped with Session 23*B* on wastes at the end of the volume.

It is unfortunate for the reactor metallurgist that fission occurs primarily in uranium, for no more obtuse metal could have been found! Fig. 30 of Foote's review paper on the physical metallurgy of uranium well illustrates this: a two-inch rod of uranium produced by swaging a cast bar elongates six times its original length merely as the result of cycling 3,000 times between 50° C. and 600° C. The first problem then is to ensure random orientation and fine grain-size; attainment of high purity and alloying can help this, and alloying can impart increased strength to withstand the internal forces created by the substitution of two atoms of fission products for one of uranium. Chiswick and Kelman's paper (557) and Pfeil's (416) report this subject extensively. Thorium, several times more plentiful than uranium, has a simple cubic crystal structure and so exhibits no such changes on thermal cycling. Carlson's very long paper on the metallurgy of thorium is exhaustive, dealing with many of the alloys in great detail and referring to the precautions to be taken in fabricating and machining this element and its alloys.

Plutonium is almost an unknown quantity metallurgically; it is a pity that there is no paper on the fabrication of the fuel elements for the breeder reactors in this volume; but the intermetallic compounds are described in paper 826.

Uranium is canned in aluminium tubes in several reactors, and we are indebted to Kiessling of Sweden for a good description of the solid-state reactions between uranium and aluminium over a wide temperature range, although we need a supplementary account of the effects of radiation on the boundary layers between these elements. Anodic coating of the inside of the aluminium can, or the provision of an aluminium silicon layer, delays interdiffusion up to 300° C. For higher-temperature operation the oxide of uranium has been considered in a short paper (559), and Howe reports (paper 825) the zirconium-clad rods for use up to 800° C. (or possibly 1400° C. for thorium–uranium systems), and the liquid metal (NaK) bonded rods in stainless steel for the breeder reactor. For lower-temperature reactors, especially the water-moderated reactors, and research reactors, uranium has been dispersed as UAl_4 throughout an aluminium mass afterwards clad in sheet aluminium to retain the fission products (papers 561 and 953 report fully on the materials testing reactor fuel elements).

The liquid metal technology holds great hopes for the future; the liquid-sodium (or NaK) cooling is essential for fast breeder reactors, while reactors employing the liquid bismuth–uranium, bismuth–thorium mixtures would—if successful—avoid the refabrication of fuel elements. There has been a lot of experience gained with Na (or NaK) over many years—it came as a surprise to me to learn that valves on all American aero-engines and on many American cars are cooled with liquid sodium. Paper 123 recounts General Electric experience on the first breeder reactor, and the problems of the important sodium-graphite reactor are fully described by North American Aviation. The liquid bismuth fuel breeder reactor is still being studied as a possibility, and paper 118 is exceptionally interesting in the descriptions of the use of titanium and zirconium as inhibitors in reactions between uranium and graphite and uranium and steel at the temperatures around 500–700° C. It is interesting to note that early use of inhibitors was developed by the General Electric of America for mercury boilers. Again, information is needed as to whether these inhibitors are equally successful in the presence of neutron flux, and metal loop tests threading through reactors are necessary.

In the Chemical Session 20, the Westinghouse paper (537) deals with the important problem of corrosion in the water-moderated power reactors operating at high temperature and shows the effectiveness of the 'Zircalloy-2', a zirconium–tin alloy, in reducing the effects of corrosion; apparently there is no complete solution in sight. Another way of avoiding chemical digestion and refabrication of fuel elements is to purify the fuel in molten metallic form by liquid metal solvent extraction—using an element such as silver which dissolves plutonium and many fission fragments, but is not dissolved by uranium. Voigt fully describes this in paper 592.

For the reactor metallurgist the interest of Vol. 8 lies in the records of Sessions 16 and 17, which dealt with the moderators and some constructional materials of reactors. There are massive papers from the United States on heavy water, graphite, zirconium and beryllium, supported by others dealing with special points of purification or analysis. This is another volume which shows the tremendous extent to which America contributed to the success of Geneva by disclosing so much secret work; but the contribution from some small countries such as Portugal and the Argentine are nevertheless important and most welcome.

Benedict surveys (paper 819) the production processes for heavy water; so far heavy water has been a by-product of processes which have borne the main cost of production. These, however, have not been and are not likely to be of a scale large enough for reactors of the future using heavy water as coolant and moderator—needing a charge of, say, 50 tons per 100 MW.; thus the Norsk Hydro Co. in the course of producing a million cubic feet of hydrogen per hour electrolytically for ammonia synthesis produces a mere 2 tons of heavy water per year. When huge quantities are needed, single-purpose processes will be required using water as the primary feed, and four of these processes are analysed in detail. There is need for further developments of catalysts to make these reactions cheap enough to compete with the by-product processes. A paper by Gaunt describes an infra-red absorption method of determining the deuterium content of heavy water, a method which could be applied to continuous monitoring.

The review by Currie *et al.* on graphite (paper 534) is very informative except on chemical analysis of trace elements. One of the major problems is the 15–30 per cent variation of the physical properties of graphite made from different sources of coke by the same processing methods. The Pechiney Co. in France reports similar variations of properties, and another paper from France deals with the estimation of boron in graphite down to a few parts in one million.

The zirconium paper by Shelton *et al.* reviews the early history of the Kroll and iodide processes for the manufacture of metallic zirconium after separation from hafnium. Initially the Kroll sponge was refined by the iodide process; but now after careful control of contaminants ductile metal is made by arc melting the Kroll sponge, and costs only £3 per lb. It is disappointing that in the section on alloys there is no reference to the important 'Zircalloy-2'. The separation of hafnium by the liquid counter-current extraction process is described; the Russian paper describes the recrystallization method of separation developed by Coster and Hevesy. No mention is made of the use of hafnium.

Beryllium production is described in papers from the U.S.S.R. and the U.S.A. The Russian method is the electrolysis of the fused chlorides (beryllium and sodium) followed by distillation of the metal *in vacuo*, and sintering of powder before hot pressing rods and tubes at 600° C.; the American method is the reduction process of the fluoride by magnesium yielding a metal of 99·5 per cent purity. Even after redistillation the metal is no more ductile than less pure samples and the conclusion is reached that, unlike zirconium, there is little hope that further removal of metallic impurities or oxygen will result in greater ductility. Alloying and the use of oxygen scavenging elements has led nowhere. The cost of the metal has been borne primarily by the beryllium–copper industry; but it is anticipated that the nuclear power industry will now cheapen production. It is interesting to learn that long exposure of the metal in the materials testing reactor (Idaho) caused no significant changes in properties.

The first half of this volume is devoted to the ores of uranium and thorium and the production of the metals, and makes interesting reading to the non-specialist. We learn that the ion-exchange methods are revolutionizing uranium ore processing plants and yield high-grade concentrates directly from the leach liquors. Florida processes ore in the form of phosphate for artificial fertilizer manufacture, so that 00 gm. of uranium per ton results as a by-product. Yugoslavia shales treated for mercury yield 136 gm. of uranium per ton as a by-product. Rich zircon ores of Brazil contain up to 4 per cent uranium. Many of the Witwatersrand ores mined for gold contain uranium (but no quantitative figures are given), and as the cost is borne by gold it is likely that uranium will now be extracted from low-grade ores. The Canadian and South Australian rich ores are mined solely for uranium, and no figures are given for these. The U.S.S.R. tells us nothing.

Thorium content of Brazilian monazite averages per cent and uranium 0·3 per cent; a very far-reaching paper (850) from the United States points out that due to the ionic radii of uranium and thorium these elements are localized in a small fraction of igneous rocks and that a high percentage can be leached from granite without digesting the rock as a whole. This opens up the possibility of extracting millions of tons of uranium; interesting, but will not thermo-nuclear reactions save us from dissolving up the world's granite?

METALLURGY OF ZIRCONIUM

The Metallurgy of Zirconium
Edited by Benjamin Lustman and Frank Kerze, Jr. (National Nuclear Energy Series. Division 7—Vol. 4.) Pp. xviii+776. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 75*s*.

IN 1948 the production of zirconium in the United States was measured in hundreds of pounds: by 953 it was measured in hundreds of tons. "The Metallurgy of Zirconium" is not only a reference book, but also gives some account of the extremely rapid scientific and technological development over this short period of time. It is an exhaustive treatise, and the editors are to be congratulated for assembling the efforts of more than fifty authors into a coherent whole.

The extraction methods, and in particular the Kroll and iodide large-scale processes, are dealt with in detail. A full chapter devoted to the latter process gives an excellent account of the development of an extraction method from virtually the laboratory scale to the full-scale production plant. This type of information is all too rare in technical literature.

Metals of interest in the field of nuclear energy are characterized by the stability of their oxides, carbides, nitrides, etc. Because of this, difficulties arise in the development of fabrication techniques; neutral heating atmospheres are normally needed, and the choice of container materials for the molten metals is very limited. In the case of zirconium, the development of arc-melting techniques capable of producing 1,000-lb. ingots has circumvented the container problem and is described in detail. Additional small-scale methods for melting are also described—namely, auto-crucible, skull, drip and levitation melting—all of which must be of interest where very reactive metals are concerned. Potential users of zirconium would do well to pay attention to the section of Chapter 6 on the recovery of scrap, which points out the many difficulties associated with reclamation of machine scrap. Powder metallurgy techniques which have proved of great value in the fabrication of beryllium and thorium, and to a lesser extent uranium, appear to be of less use in the case of zirconium but are obviously well developed. Zirconium of high purity is very ductile at room temperatures, and an account is given of a wide range of cold-working operations. Despite the great affinity of zirconium for oxygen at elevated temperatures, hot-working operations can apparently be carried out without the use of protective furnace atmospheres. Pickling in acid is afterwards required to remove the contaminated surface layers.

The chapter on the physical metallurgy of zirconium and its alloys leaves little to be desired, the only physical constant which proved difficult to find being the X-ray density. Partial or complete equilibrium diagrams are given in the appropriate section for thirty-two binary alloy systems, and brief results are given for a further five systems. Engineering data are given at length in the chapter on mechanical properties, and the marked effect of minor amounts of contaminants upon these properties is emphasized. These contaminants have an equally marked effect upon the corrosion behaviour of zirconium, as detailed in Chapter 11. Most of this latter information is made available for the first time, having been previously placed in the category of 'Classified' material. This is also true of a good deal of the information in other chapters, as is stated in the introduction.

It is difficult to find fault with this book. The overall impression it leaves is one of admiration for the technological achievements described; perhaps this feeling is tinged with envy for the scientific resources of the United States, where an effort involving at least fifty senior scientists and technologists, complete with supporting staffs, could be mounted to investigate the metallurgy of just one metal.

INTRODUCING GEOLOGY

Geology and Ourselves
By F. H. Edmunds. Pp. 256+12 plates. (London: Hutchinson's Scientific and Technical Publications, 1955.) 21*s*. net.

MR. F. H. EDMUNDS in his long experience on the staff of the Geological Survey of Great Britain has met with a lively interest in his science and its economic applications. Accordingly, he has written this introduction for the layman to show the importance of geology in everyday life.

Almost half the book is devoted to a simple general survey of geology. A short account of the early history of the subject is followed by a neat splitting of modern geology into its four main compartments : physical geology ; mineralogy and petrology ; palæontology ; and historical geology. This is followed by chapters on geological surveys and maps, on the relatively new sciences of geophysics and geochemistry, and finally an interesting short chapter on the methods of drilling boreholes in the ground.

The second half of the book introduces economic geology, and the author is able to draw upon his practical experience in the selection of some suitable British examples. There are chapters on water supply, building materials, engineering geology, coal mining, ores, petroleum geology, and on geology and agriculture. The penultimate chapter refers to a number of other aspects of applied geology, such as the problems of mining subsidence, but concludes strangely with a few paragraphs on early man. A final chapter touches briefly on the possibilities for amateur work in geology.

This book, as the author writes in his preface, is "in no sense a text-book". The second part would justify its inclusion in a school library, but otherwise it is suitable only for the general reader. Such a book, intended for the layman, should be attractively illustrated and interestingly written. Compared with some of the beautifully illustrated popular science works to which we are becoming accustomed, this book makes a poor impression. Of the photographs a few, such as the one of a fissure produced by mining subsidence, are impressive ; but others, such as the small aerial view of King George V Dock during construction, are of doubtful value. The diagrams throughout are uninspired, and the writing, though clear, is pedestrian in style.

Errors are few, though Chapter 4, on historical geology, contains several. It is stated, for example, that Great Britain "contains representatives of every one of the geological systems from the Cambrian upwards", while later, under "Miocene System", we find that "there are no Miocene deposits in Great Britain". In the stratigraphical table on pp. 76–77 Oligocene rocks are incorrectly referred to as being restricted to the Isle of Wight. In this table, too, the Devonian rocks are curiously listed stratigraphically as comprising Lower Old Red Sandstone, Marine Devonian, and Upper Old Red Sandstone. Finally, the placing of the Downtonian Series in the Silurian instead of in the Old Red Sandstone is not in accordance with the practice now followed by British workers on these rocks. There are several misprints in page and plate references which could easily have been avoided. The contents list on p. 5 contains two of these incorrect numbers.

C. H. HOLLAND

PROTECTIVE CURRENT TRANSFORMERS

Protective Current Transformers and Circuits

By P. Mathews. (Advanced Engineering Textbooks.) Pp. xv+253+4 plates. (London : Chapman and Hall, Ltd., 1955.) 36*s*. net.

MEMBERS of the staff of the British Thomson-Houston Company are preparing a series of advanced text-books on electrical engineering, and the second book of this series covers the subject of protective current transformers. This is the first book of any standing on this subject and will b welcomed by all concerned with the design and us of protective gear for the wealth of information i contains, supported by the authority of a leadin designer. Mr. Mathews does not shirk any of th difficulties of his subject and has written his book fo the benefit of workers in this field of engineering. I is scarcely to be considered suitable for engineerin students. The title of the book suggests two subjects but it is clear that the author is mainly interested i transformers : circuits are discussed only in so far a they affect the transformer design. It is perhap somewhat surprising that the author does not giv an introductory chapter surveying the whole field o protection and indicating the function of the transformer in this field, but apparently he assumes hi readers to be already well versed in the genera subject and he starts immediately on the transformer

The book is divided into two parts, the first dealin with design for steady-state conditions and the secon with design for transient conditions, which ar becoming more important with the increasing use o high-speed protection. Each chapter has its ow references—a procedure which is preferable to collecting all the references in one block.

The author bases his treatment on the linea theory of current transformation but does not mak clear why the vector theory is unsatisfactory. Hi development of the linear theory is on the whol clear and easy to follow except for some awkwar jumps. For example, he introduces ratio error befor he has defined ratio and he passes from the genera theory of coupled circuits to the theory applicable t single turns only without any clear dividing line This leads him into a minor error when he state that the leakage inductance of a toroidal secondar winding with respect to a bar primary is zero, statement which is only true for a single-tur secondary, although it is a close approximation for single-layer secondary. For multi-layer secondar windings the leakage inductance is negative. It i noteworthy, however, that minor blemishes of thi kind only occur in relatively unimportant places, an the author has evidently taken great trouble t develop a sound treatment of the important parts o his subject. The reading of the book is perhaps mad a little more difficult by the author's ruthless disregard of the standard symbols of the Britis Standards Institution. Some sympathy may well b felt for him when he finds himself at variance wit this Institution over the irrational definitions of rat error and the sign conventions for phase angle transformers adopted by this body ; he is on les sound ground when he uses a small 'e' to indicat current, small and capital letters indiscriminately fo r.m.s. currents, $\log_e$ instead of ln, and other variatio from standard usage. The coming of new words always an attractive occupation and the author ha allowed himself the luxury of creating the wor 'decroachment'. Whether others will accept th rather ugly word remains to be seen.

It is inevitable that the minor faults mentioned i this review should appear disproportionately im portant ; but there appear to be no major faults an the treatment of the transient operation of tran formers, in particular, is excellent.

It would not be out of place to include a word praise for the publishers and printers for the attracti lay-out of the book, the pleasing contrast betwee the type and the paper surface and the very fe errors.

A. H. M. ARNOLD

WORLD POPULATION GROWTH AND ITS REGULATION BY NATURAL MEANS*

By DR. C. B. GOODHART

University Museum of Zoology, Cambridge

RECENT discussions on the future of humanity have tended to be rather discouraging, and there are plenty of eminent authorities who are prophesying disaster. World population is now multiplying so fast that at the present rate it is bound eventually to outgrow its food supply, however much that can be increased, and then famine and disease will intervene to prevent further population growth, unless indeed the hydrogen bomb provides an effective and relatively humane alternative to more orthodox Malthusian agents. The only solution seems to be the immediate and universal application of a policy of deliberate family limitation, and few are so optimistic as to believe that this is either practicable or likely to be effective in time to save us from the crash.

It is important to remember, however, that population increase is primarily a biological phenomenon and that the arguments of Malthus, though mathematically sound, are based upon the assumption that man has some specific and constant rate of reproduction which will be the same in the future as in the past unless it is artificially altered. This is a biological assumption that remains to be proved, so I wish to consider whether there are any conceivable ways in which it could be falsified by natural, as well as by artificial, means. Predictions in human demography are notoriously uncertain, and Malthus's disregard of possible increases in production proved him wrong during the past century, so we will do well to examine rather carefully any other assumptions upon which his theories rest.

In the first place we must recognize that man has a rather low reproductive rate, compared with most other animals. A woman who has ten children is reckoned highly fertile, and with fifteen she approaches the prodigious, and yet the domestic pig, of comparable size and on much the same diet, produces as many every year. In man, multiple births are rare, women are fecund for only about half their lives, conception may be inhibited during lactation and more or less complete sterility is surprisingly common. These checks on fertility must be the result of natural selection, for if there had been any real overall selective advantage in higher fecundity it could easily have been evolved. Women are well adapted anatomically for nursing twins, and the tendency to have them is certainly inherited, so that their comparative rarity must mean that, owing probably to higher mortality, there can be no real selective advantage in multiple births even though, potentially, they could increase fertility. Is it possible that the mean fecundity of man could be still further lowered by natural selection? If it could be halved during the next few generations that would probably solve our problems. At first sight this seems unlikely since we usually think of evolution as a slow process working through hundreds of generations; but there is an exception to this rule, where populations are already genetically heterogeneous for the characters involved, especially where the heterogeneity, or polymorphism, results from a balance of advantage between opposing genetic factors. Here, any change in selection pressure may alter the balance quite rapidly and lead to large changes in the composition of the population by altering the proportions in it of the two opposing types.

In Great Britain, for example, we are polymorphic for hair colour and texture: dark, fair and red hair, curly and straight, are all common genetically inherited characters, and quite closely related races may have markedly different proportions of the various hair types, which, if they were subjected to selection, would not remain constant from one generation to the next. We are certainly also genetically heterogeneous for factors affecting stature, though here there are many genes involved and there is a graded series of different heights without any clear breaks as are found for the different hair types. The mean stature of the population seems to have increased by an inch or two since the Middle Ages, and this change may well be the result of natural selection if large people are more affected by food shortage and bad conditions of life than are small; improved conditions now allow more of the largest individuals to survive, so that the average height of the population has increased. There is plenty of evidence that man is also genetically heterogeneous for factors affecting fertility, and if the selective value of the different types were altered there would be a similar change in the mean fertility of the population, quite apart from any artificial restriction of family size. To take an extreme example, one type might have a mean family size of 10, and the other of 2 (though actually, as for stature, there will be a whole series of intermediates), so that a race with 90 per cent of the high fecundity type and 10 per cent of the low would have a mean family size of more than 9, while in another, with the proportions reversed, it would be less than 3. If for any reason these proportions were to be changed in the course of time as a result of natural selection the mean fertility would be greatly altered, and if the selection was strong an effect would be shown after only a few generations. In human beings, of course, fertility depends not only on natural fecundity but also on psychological and social factors which may limit the fertility of physiologically fecund individuals; but these other factors, like physiological fecundity, may well be at least partially inherited.

The present rate of increase in the numbers of man is quite exceptional; the population of the world has certainly doubled and may have trebled itself in the last half-dozen generations; but the increases have not been the same in all races and classes of mankind. We rightly pay most attention to the teeming millions of Asia and Africa which are now multiplying at such an extraordinary rate; but during the same period many races have had stable or declining numbers, and some are heading towards extinction. The African Bushmen, Australian Aborigines, Red Indians and Eskimoes should not be forgotten when the present mean rate of world population increase is extrapolated into the future. A century ago in Western Europe we had as high a rate of natural increase as any race before or since, and yet it has been arrested and even reversed, admittedly partly by artificial means, in four generations, and the same could happen with other races as well.

---

* Paper read on September 5 before Section D (Zoology) of the British Association meeting at Sheffield.

The selective advantages of fecundity are obvious and they are particularly strong in dense populations living under unhygienic conditions and subject to acute epidemic disease and a high rate of infant mortality. Cholera and plague strike indiscriminately at rich and poor, strong and weak, alike, and where only a fraction of the children born can hope to live to rear families of their own, only the larger families will be represented in the next generation, irrespective of the quality of the individuals concerned, for small families are liable to be wiped out completely. Thus in these dense disease-ridden communities selection for fecundity is relatively stronger than for most other qualities. In primitive races of pastoral nomads or hunters, however, who live widely separated under hygienic conditions, disease may be less important and the principal limiting factors will be periodical shortages of food. Here fecundity loses much of its selective advantage compared with such other qualities as strength and intelligence, and may even become a liability. In a bad year an Eskimo might be able to find enough food to keep one or two children from starving; but if it had to be shared among ten all would be weakened by hunger and die. It is just these primitive nomadic peoples that seem unable to recover their numbers after they have been afflicted with diseases introduced from outside. Individually they are often more virile and fitter in all respects but fecundity, compared with other races living a much less healthy life in dense centres of population, who seem able to replenish themselves almost immediately after the most disastrous epidemics. Yet we must remember that for 99 per cent of his history man has lived as a nomadic hunter and food collector; the densely settled agricultural and urban communities characteristic of the last few millennia are really a very recent development. We cannot, therefore, assume that the high fecundity found in these dense and unhealthy aggregations of population are necessarily typical of the species; it might well have been evolved in response to these rather special conditions, and if selection pressures alter in the future, reproductive rates would alter too and might revert to the lower levels characteristic of our remote nomadic ancestors which would be more 'typical' of the species as a whole. Improvements in medicine, which would allow more children to reach maturity and so lessen the risk of extinction of lower fecundity lines, would diminish the relative advantage of high fecundity, which will have been disproportionately increased when man, at the dawn of history, abandoned his former more healthy nomadic way of life.

However, it is notorious that declining numbers are found not only in primitive peoples brought into contact with civilization, but also in many of the most advanced nations and classes, whose declining numbers certainly cannot be attributed to genetical selection by famine. It has been suggested that the conditions produced by civilization and a high standard of living may in themselves be unfavourable to fertility, and it is certainly true that the more or less stable population in north-western Europe at the present time owes much to the introduction of artificial methods of family limitation which are only practicable in relatively advanced and prosperous communities. However, the universal rule of declining numbers in advanced civilizations dates back long before the discovery of artificial means of bringing it about, and we must not overlook the possibility that those qualities leading to success in man may have become genetically correlated with relatively low fecundity, and there are some *a priori* arguments in support of such a view.

Under most conditions high fecundity has a clear selective advantage in itself quite apart from any other qualities with which it may be associated, but the less fecund lines will not survive unless they have other hereditary qualities of high survival value to offset the selective disadvantage of low fertility. It is obvious that a man with a dozen children, however ill-favoured, has a better chance of leaving grandchildren, as unpleasing but as fecund as their parents than his neighbour with one plain daughter; but an exceptionally good-looking and intelligent young woman has little difficulty in finding a husband, even though she may lack brothers and sisters. Brains and beauty, virtue and sex-appeal, wealth and social position—that does not exhaust the list of attributes that may influence a man in the choice of his bride before he considers her capacity to present him with a dozen children.

Francis Galton once showed that, in the British peerage, wealth in women was correlated with infertility. An heiress by definition comes of an infertile family, for otherwise there would be many to share her wealth, and many noble families have become extinct through the love of heiresses whose riches were matched by their infertility. We may now put forward another rule, that not only wealth but also nubility in women is likely to be associated with infecundity. Attractive girls will usually marry, and the fecund will have large families while the less fecund will do their best and will certainly leave some descendants in future generations. Unattractive but highly fecund girls will be less likely to marry; but those that do will have plenty of children so that, as a group, the unattractive but fecund will also leave descendants. However, the group that is both unattractive and infecund will be at a double disadvantage and so will tend to be under-represented in future generations. Consequently in each generation, owing to the elimination of this last group, we would expect to find that the mean fertility of nubile and attractive mothers should be below that of the less attractive. This proposition cannot easily be proved. There seems to have been a regrettable lack of research on nubility in women; but as an illustration of what is meant we may consider the breeding record of King Louis XV of France and Mme. de Pompadour, the subject of a recent biography by Miss Nancy Mitford. The King took as his wife the Princess Maria Leczinska of Poland, aged about sixteen and probably deliberately selected for dynastic reasons on account of the splendid record of fertility in her family. She developed into a plain, healthy and rather dull woman who enjoyed the King's not undivided attentions until, at the age of twenty-seven, her reproductive career ended with ten children of whom six survived to maturity. Mme. de Pompadour then took over the far from nominal duties of *maîtresse en titre*, which she performed to general satisfaction for nearly twenty years. She was aged twenty-three when she met the King and had had one child who died young; but though she is said very much to have wanted children by the King, and had several miscarriages, she had no further living children; the King himself left plenty of evidence elsewhere of his own continued fecundity. Mme. de Pompadour, who was considered one of the most attractive, intelligent and accomplished women of her time, came of a bourgeois family that had risen in the world to a position of considerable affluence, and her own mother, married at an early age and renowned more for her beauty than her virtue, herself had only two children. The contrast in fertility between the nubile mistress and the unattractive Queen is striking.

Using similar arguments we would expect that most other human characteristics leading to success in life will become genetically associated with lower fecundity, quite apart from the fact that in more advanced communities low fertility in itself usually results in a higher standard of living.

We know that in animals and plants genetic characters are usually only maintained at the highest level if they are subject to continuous selection, and that there is a loss of fitness as soon as selection pressure is relaxed; this process has been called 'genetical erosion' by Prof. S. C. Harland. There is probably an example of this effect in man with milk yield. A considerable number of civilized women are unable to feed their own babies, although in more primitive races mothers seldom have this difficulty, so long as they are adequately fed. The easier life of civilized women is unlikely to be the direct cause of their inability to produce sufficient milk; but, since artificial feeding is now perfectly satisfactory, selection against low milk yield has ceased. In less advanced peoples, on the other hand, the only children to survive infancy are those whose mothers did have an adequate milk flow. In domestic cows milk yield has been greatly increased in a few generations by deliberate selection, and in civilized man the reverse seems to have happened, also in quite a short time, as soon as selection was relaxed. So also, if selection for the highest fecundity is relaxed, we would expect to find a fall in the average fecundity of the population, as is in fact seen in advanced races with low mortality.

I have suggested that, in man, the more desirable qualities are likely to become genetically associated with lower fecundity, and that there is good evidence that man is genetically heterogeneous for factors affecting fertility. It is likely that this heterogeneity will be maintained by a balance of advantage between higher fecundity on one hand and other qualities of high survival value associated with lower fecundity on the other. It is indeed hard to see how the observed heterogeneity could exist at all unless there was this compensating factor, for without it the lines of lower fecundity could never survive in the face of natural selection. Any equilibrium of this type will be an unstable one, and will be disturbed if the mortality-rate in early life is altered; if it is lowered the *relative* advantage of high fecundity will be diminished, and so we would expect the lower fertility lines to show a proportionate increase.

All this, of course, is rather speculative, and since experiments are impossible really conclusive evidence one way or the other is very difficult to obtain. It may, however, be instructive to consider the population problems of Ireland, which do suggest that selection against fecundity may have had important results over quite a short period. Before 1750 the native Irish lived in conditions of the direst poverty, and must have had a high infant mortality with correspondingly strong selection in favour of fecundity. The introduction of the potato then raised the standard of living, and there was an extraordinary increase in the population, similar to, but greater than, that occurring at the same time in England and elsewhere. In Ireland, however, the increased population supported itself almost exclusively on this one food crop until in the 1840's, in the words of H. G. Wells, "the weary potato gave way under its burden" and was blighted by disease, with the inevitable result of a disastrous famine followed by disease and emigration. In the normal course the formerly highly fertile population should have replenished itself rapidly and resumed its growth with only a slight check; but this did not happen, and the population of Ireland has continued to decline until now it is barely half of what it was in 1840, though most neighbouring countries have doubled their populations during the same period. A probable explanation of this unexpected decline is that since the famine there has been rather strong selection against large families, though artificial restriction of numbers has probably been less important in Ireland than elsewhere.

In the first place, large families are likely to have been worse affected by the famine than smaller ones; where there were numerous children to share the little food available all would be weakened by starvation and may have died. Secondly, and even more important, emigration will have been selective. An only son who has hopes of inheriting the family farm, however impoverished, will not readily abandon it; but if it is to be shared among half a dozen brothers, most of them will be inclined to seek their fortunes elsewhere when times are bad. By 1850 the population of Ireland would have lost most of its more fecund members, leaving the task of replacement to the genetically less fecund who remained. For various special reasons this process is likely to have been continued. A girl's chances of marriage depended largely on the size of her dowry, and that was inversely proportional to the number of sisters who had to share what could be spared. The peasant economy required that adult children should remain on the family farm as unpaid workers, and this tended to advance the age of marriage and so to reduce the number of children born. That in itself was an important, though not a genetical, factor in limiting population; but it is also likely that the more enterprising and virile young men and the more highly sexed girls will have rebelled against these restrictions and left for abroad. The present low fertility in Ireland seems to be due largely to late marriage and failure to marry rather than to low fertility in those women who do marry young, and it is said that many people in Ireland nowadays are 'not the marrying type'. Their infecundity may be psychological rather than physiological, but it is none the less real, and psychological characteristics can be inherited just like anything else; their preponderance in the population could well be the result of selective emigration of those that *were* 'the marrying type'. This process, once started, will continue, for a girl who wishes to marry but lives among a lot of confirmed bachelors will be all the more likely to try her luck elsewhere. Although economic impediments may be given as the reason for late marriages, they are unlikely to be its primary cause, for a much lower standard of life than that at present enjoyed in Ireland does not prevent marriage and procreation in many other countries, and it was not effective in Ireland before the emigrations. Nor is the influence of the Church to be neglected, the call to the convent or the priesthood will no doubt be all the stronger if there is little in the way of worldly wealth to be left behind, and it would not be surprising to find that the mean number of brothers and sisters to each priest and nun in Ireland was significantly higher than for married people of the same age-groups.

There is another important argument in favour of our suggestion that the selective disadvantage of lower fecundity is compensated by other characters of high survival value associated with it, and that is in the inheritance of intelligence. It is well known that in Great Britain at the present time really large families of ten or so children are often of low quality and below average in intelligence, and it has been suggested that since the less intelligent seem to be the most prolific this means that the average level of intelligence of the population will be falling, and that 'civilization is rotting at the core'. In point of fact the only really large-scale direct observations that have been made, on the intelligence quotient of school children in Scotland in 1932 compared with 1947, failed to show any sign at all of the expected fall in mean intelligence. This has been considered a very puzzling and unexpected result; but it is puzzling only on the assumption that the fact that the largest families are to be found among less-intelligent people means that as a group the less intelligent will leave proportionately more descendants in each generation. This is by no means self evident for, quite apart from possible higher mortality in large families of low quality, the data refer only to the low intelligence of the largest families but give no information about the mean family size of the less intelligent as a group. If intelligent people (though fewer of them have really large families) more often marry and have small families than do the less intelligent, they may well leave as a group as many descendants as the less intelligent, of whom a few have the largest families but a higher proportion leave no children at all. If this really is what happens, the mean level of intelligence of the population should remain constant and the Scottish results are puzzling no longer.

We might be able to get direct evidence of differential survival in high- and low-fertility lines in populations for which statistics are available of the distribution of family size two or three generations back. From these we could derive a figure for the number of great-grandchildren to be expected by women who had families of various different sizes, which could be compared with the number of maternal great-aunts and -uncles actually possessed by a sample of children from the latest generation. If they were below the expected number this would confirm our hypothesis that relative infertility a few generations back had been compensated for by better survival and reproduction among the descendants of the infertile families.

To sum up, we have suggested that human populations are genetically heterogeneous, or polymorphic, for factors affecting fertility, and that this heterogeneity is maintained by a balance of selective advantage of high fecundity on one hand and other factors of high survival value associated with lower fertility, on the other. These other factors are seen to be mainly such qualities as intelligence and nubility, which by increasing the chances of success in life and of marriage should compensate for lower fertility, with the further possibility that better health and lower mortality may also be involved. In addition, the lower fertility lines may have a larger proportion of small families with fewer individuals leaving no children at all, so that the difference in mean fertility will be less than is suggested by a consideration only of the largest families in each group. An objection may be raised here, that there is little reliable evidence of this hypothetical association of desirable qualities with lower fecundity, and that to outweigh the very real disadvantage of low fertility the association should be too obvious to be overlooked. To this I would reply by asking another question. We know that more or less complete sterility is surprisingly common, affecting perhaps 10 per cent of married couples, besides those people who never intend to marry and who must be considered psychologically infecund. Such infecundity is generally intrinsic and not due to injury or disease, and it is therefore likely to be at least partly conditioned by inherited congenital factors. Since selection against infecundity is absolute, and stronger than for many rare and harmful though not actually lethal genes, how could any genes responsible for it possibly occur at anything like their present level in the population unless the lines that tend to produce infecund individuals had some important compensating advantage as compared with other lines in which the incidence of infecundity was lower?

If this genetic heterogeneity is maintained, as I have suggested, by a balance of advantage between high and low fecundity, the balance will be an unstable one, and the lines of high fecundity but otherwise of lower quality will be especially favoured in dense populations where mortality from disease is high and indiscriminate, and where small families may be entirely wiped out by disease before benefiting from their presumed greater intelligence or nubility. Such conditions have been experienced by man only during the past few thousand years, so that in many parts of the world at present the mean fecundity of the population is likely to be disproportionately high, compared with our more remote ancestors who lived a healthier life in which strength, and intelligence, rather than mere fecundity, had a higher survival value. Now that disease is being mastered and early mortality is becoming negligible, even though we continue to live in dense communities, families of lower fertility but otherwise of good quality will survive so that they can take full advantage of these better qualities in competition, and the balance of advantage should shift away from the lines of highest fecundity but otherwise of lower quality. It is to be expected, therefore, that at first when new medical techniques are introduced into formerly disease-ridden and fecund populations there should be a rapid rise in numbers; but as the less fecund lines begin to benefit from the new situation, and increase, the mean fertility should fall and the population should taper off to a new position of equilibrium at a much higher level of numbers and, perhaps, with a higher level of intelligence and other desirable qualities.

Sir Charles Darwin, in his stimulating and provocative book "The Next Million Years", adopts the Malthusian argument that, in the long run, human population must always be limited by food supplies, and there will always, or at any rate usually, be a large "starving margin", and he concludes with the challenge that "Anyone who disagrees with my forecast must try to get beyond a vague optimism. . . . In particular he must find a really solid reason which shows how the threat of over-population will be avoided . . . or else he will find that his imagination has gone so far out of the realms of reality that it contradicts the physical or the biological laws of nature".

I have tried to show that there may be, if not really solid reasons, at least plausible arguments not inconsistent with the biological laws of Nature, on the basis of which we may question the fundamental Malthusian assumption that human fecundity has some constant and rather high mean value which could only be altered by artificial means. It is at least conceivably possible that prosperity may provide its own solution to the problem by being the cause of a natural lowering of the rate of increase of the population. Whether my arguments have carried conviction, or whether we continue to believe in the essential correctness of Malthus's analysis, our actions at least will remain the same. No one seriously believes that we can or should deliberately limit increases in world food supplies, nor that we should withhold medical discoveries from over-populated regions, however much many may fear that the benefits they bring will in the end prove illusory. Nor does anyone doubt that these benefits will be the cause of an immediate and, in some parts of the world, at least, an undesirable increase in the present population, which should be restricted by all legitimate means, however much opinions may differ as to what means are legitimate. All I am suggesting is that it is just possible that what we are in any event bound to do may, if we do it in time, not lead our descendants inevitably to disaster.

EFFECTS ON AGRICULTURE OF CHANGES IN THE BALANCE OF NATURE

THE morning session on August 31 of Section M (Agriculture) of the British Association during the Sheffield meeting was devoted to effects on agriculture of changes in the balance of Nature. Mr. E. M. Nicholson, director-general of the Nature Conservancy, opened the session with a paper on "Ecological Research and Farming". He emphasized the common interest of the farmer, forester and nature conservationist in an adequate and well-directed programme of fundamental research into the basic processes of Nature, including soil building, the balance of supply and demand for water, erosion, and the natural control of animal populations. Successful management of Nature, whether for food-growing, timber-growing or conservation, is dependent on a greatly improved knowledge of such processes, which may prove the key to an increase in the rate of formation of natural 'capital' and thus raise the potential 'income' in the form of renewable resources, including vegetation and water. The Nature Conservancy's researches on woodland soils, for example, include studies of the role of different tree species as soil improvers and soil impoverishers, and comparisons of productivity under different species of hardwood trees and conifers compared with weight increases shown by sheep on identical plots scattered within the same experimental area. Other factors being measured include the amount of water used by plantations of trees which would otherwise be available for stream-flow and for water-supply undertakings. It is possible to measure the potential yield of water supply under alternative land uses and to analyse the parts played by, for example, evaporation and transpiration. The Nature Conservancy is now recording potential evapo-transpiration daily in both the east and the north-west Scottish Highlands and in Wales and the Pennines, with results differing considerably from those which had been theoretically predicted.

The maintenance and enhancement of natural 'capital' involve studies now in progress at Moor House Field Station on the management of peat moors and the part played by different types of land management and land use in causing or preventing erosion, which is occurring at a formidable rate, for example, in the Trough of Bowland. Tree stumps and cattle horns of prehistoric age are found even above the 2,000 ft. contour, far above the level at which either exists to-day, and there is little doubt that trees of some sort, if only rowans, alders and willows, could under suitable land management cover some of those areas again, interspersed with improved herbage. In some areas fertility might be raised by making good the chance absence of some soil-improving animal or plant, such as the small hardy strain of wild white clover adapted to high altitudes and heavy rainfalls which has recently been found in North Wales (cf. *Nature*, 176, 596; 1955).

In discussing the balance of Nature, Mr. Nicholson emphasized that it must be remembered that every natural event, whether or not caused by human interference, opens certain doors and closes others. Civilization, unfortunately, closes many doors permanently by excessive inroads into dwindling residues of so-called waste lands which are the last remaining reservoirs of irreplaceable stocks of genes evolved over millions of years.

Mr. Nicholson criticized popular attitudes towards pest control and quoted results obtained during nearly thirty years showing that the population of the heron in England and Wales has without control measures been effectively held at between 4,000 and 4,700 breeding pairs by ecological limitations. On the other hand, the wood pigeon has been greatly favoured by the systematic killing of its predators, such as sparrowhawks, and by the additional cover provided for breeding in young plantations. Control measures would be extremely difficult in face of these ecological stimuli to expansion. Rabbits became a major pest directly owing to human encouragement, and future rabbit populations will depend mainly on whether we have the will to prevent them, as we can, from returning to former levels.

Nature and its study should be regarded as intimately concerning farmers and foresters, who should aim at understanding and working with Nature, rather than using too many mechanical and chemical short cuts. A moralizing attitude towards our fellow predators on the Earth is out of place, and more understanding should be shown of their important role. As the fine and all-embracing tradition of the great estates has lost its impetus, ecological research may become the basis of a new and equally fruitful outlook, reconciling needs for growing food and timber with the need to keep the country worth living in for all its creatures, including people.

Dr. I. Thomas, of the Ministry of Agriculture, Fisheries and Food, read a paper on the "Natural and Artificial Control of Vertebrate Pests of Agriculture". He referred to that widely used and dangerous expletive, 'vermin', and gave illustrations of the different categories in which predators must be placed according to whether the point of view is that of growing crops or preserving game. In discussing the economic balance-sheet in Britain for the rabbit, he pointed out that while on the credit side rabbits have been estimated to yield products valued at £15 million annually, probably less than £2 million of this accrued to agriculture. On the debit side, estimated losses before myxomatosis ranged between £45 and £60 million. Rabbit trapping had, especially in its early stages, killed large numbers of predators, including foxes, weasels, stoats and polecats, and some of these predators had been exterminated over certain areas, thus helping greatly to enable the rabbit population to get out of hand. Dr. Thomas gave figures showing that the disappearance of rabbits has not greatly affected either the numbers of foxes or their depredations on livestock.

Dr. Thomas said that where rabbits have been seriously reduced, wood pigeons are now perhaps the farmer's greatest vertebrate pest; yet man has created the conditions for pigeons to multiply. Increased acreages under brassica and pea cultivation have provided much additional attractive food, and it is difficult to protect these crops by methods which are free of risk of killing game such as pheasants. More than 2½ million wood pigeons were reported to have been shot in England and Wales in 1955 and 445,000 during the first quarter of 1956. In this quarter alone, the cartridges probably cost more than £28,000, and 50 per cent of this sum could be claimed in subsidy. Adding this to the agricultural damage (which is very heavy also on, for example, clover leys), wood pigeons are costing Great Britain large sums of money. Dr. Thomas pointed out that while rabbits can be controlled estate by estate, relief from wood pigeon damage requires control over the whole national pigeon population. There is, therefore, little ground for optimism on this problem.

In a paper on "Insect Pest Balance in Agriculture", Mr. A. H. Strickland, of the Plant Pathology Laboratory, Harpenden, Herts, referred to the difficulty of relating the mathematical theories put forward by Lotka, Volterra, Nicholson and Bailey regarding growth and decline of populations to biological data so far available. Proponents of the probabilistic school have suggested, for example, that plagues of a grasshopper *Austroicetes cruciata* would occur in certain favourable areas five or six times in a century, but there is no way yet of forecasting when a plague will occur. Little work has been done so far on natural populations in the field; but ten years ago the National Agricultural Advisory Service Conference of Entomologists started routine assessments of the annual peak population densities of about a dozen insect pests throughout England and Wales, and six years ago the scheme was widened somewhat in scope to include detailed work on population density in relation to economic damage. In 1946 an 'Extensive Survey' was begun of the cabbage aphid (*Brevicoryne brassicae*), based on an annual random sample of about a hundred unsprayed brussels sprout crops throughout Britain. From 1951 this was supplemented by field-plot experiments set up in commercial sprout fields in the main sprout-growing areas. The results to date show that damage by cabbage aphid to brussels sprouts alone is equivalent to 4,500–10,500 acres a year, the average annual financial loss over the past ten years having been £868,000. Organo-phosphorous insecticide spraying, wherever economically justifiable, might have reduced this loss to about £500,000.

Ten years extensive survey has also been made of frit fly (*Oscinella frit*) infestation at harvest, and yield samples are being threshed at Rothamsted for the fifth season. Four experimental treatments have been tested. It appears that, on average in England and Wales, about 3 per cent of oat shoots are killed and about 5 per cent of oat grains are damaged by frost and second-generation larvæ respectively. This implies losses of 1·8 cwt. per acre from shoot destruction and a further 3·5 cwt. per acre from grain damage. The frit flies are thus estimated to cost farmers in England and Wales some £10 million annually. Complete frit control could raise the average national oat yield from 18·6 to about 24 cwt. per acre.

Mr. Strickland emphasized that toxic chemicals are at best palliatives, and are unlikely to provide a permanent solution, which must be sought by changes in agricultural practice leading to conditions less favourable to a high rate of increase of the pest. He cited A. Milne's recent findings that the sheep tick (*Ixodes ricinus*) can be largely controlled by minor alterations in flock management reinforced by re-seeding of old moorland pastures, while the wheat bulb fly *Hylemyia coarctata* can also be affected by suitable rotational and cultural practices. Aphid infestations can be shown to be less severe on fields of five acres than on larger fields, and even drilling a few rows of a cereal at appropriate intervals can mitigate losses from aphids. Finally, Mr. Strickland referred to the recent eradication of the screw worm *Callitroga hominivorax* in Curacao by releasing 16 million pupæ sterilized with gamma rays so that the normal females with whom the sterilized males mated laid sterile eggs. He concluded that further advances in understanding the environmental factors which prevent insect pests from increasing to an unlimited extent depend largely on development of co-operative field-work on the lines recently adopted in Britain.

There was an interesting discussion on a wide variety of topics arising from the papers. Mr. Cook (Ceylon) described difficulties met in coconut research from an even larger pest, the elephant, breaking into seed gardens despite deep trenches, powerful electric fences and other obstructions which were easily circumvented. Noise and the smell of burning rubber tyres appeared the best deterrents. Cattle had been induced to cease eating experimental plants by adding a special food supplement to their normal grazing diet.

Several speakers expressed concern over the problems of reconciling current game preservation patterns with agricultural needs, and asked that the subject should be explored.

This experiment in bridging gaps between the ecological and agricultural approaches was regarded as well-worth while, and the convergence of the views expressed from such different angles by the three speakers was remarkable, especially as regards the need for studying pest and other problems from an environmental or ecological point of view, rather than seeking chemical or mechanical magic wands.

SHEFFIELD LABORATORIES OF THE BRITISH IRON AND STEEL RESEARCH ASSOCIATION

OPEN DAYS

THE Sheffield laboratories of the British Iron and Steel Research Association are concerned mainly with research on steelmaking, metal working and ferrous metallurgy and are also a base for a section which deals with technical inquiries and investigations on the uses of iron and steel. They form one of the Association's five establishments: research on ironmaking, engineering, metal surfaces and coatings, with supporting departments of physics, chemistry and operational research, is done in London, Swansea and Middlesbrough, and the administrative headquarters are in London.

Open days were held at the Sheffield laboratories during September 6–7, when the opportunity was taken by a large number of visitors to view the work going on there. In the same building, and sharing the Association's general services, are three autonomous co-operative research organizations: the Cutlery Research Council, File Research Council and the Coil Spring Federation Research Organization.

Steelmaking

The Steelmaking Division is concerned with the hot metal when it leaves the blast furnace and until it has been turned into ingots. Current researches deal with the operation of open-hearth furnaces and electric-arc furnaces, the chemistry of steelmaking in each, and the problems of ingots and ingot moulds. Considerable emphasis is placed on the combustion problems of open-hearth furnaces, which produce about 90 per cent of steel in Great Britain. Research in the Association has shown what are the essentials of good burner design, and this knowledge is being widely used in the industry. Sulphur pick-up from the fuel and heat transfer are being studied on a 1/12 scale open-hearth furnace model.

The melting shop at the Association's laboratories houses a 10-cwt. basic electric-arc furnace, which has been used for studying the effects of different power inputs, changing the diameter of the electrodes, the height of the furnace, etc. Other work is concerned with desulphurization and close contact is kept with the more fundamental work on slag-metal reactions in the electric process, which is being carried out in London. The way in which mould dressings work has been observed by high-speed photography through a 'Pyrex' plate let into the side of a mould, and the properties needed in a mould dressing to give a good surface to the ingot have been determined.

During recent years, processes for continuous casting have been developed rapidly, and at least four experimental plants are working in Britain, two of which use a method patented by the Association. Research on the continuous-casting plant at the Sheffield laboratories includes the effects on quality of cooling-rate and of speed and temperature of casting.

Metal Working

The Mechanical Working Division is concerned with forming processes by which the ingot is made into a finished product. The processes comprise rolling, forging, extrusion, wire drawing and sheet metal working. The research also covers the plant and tools of metal working, and the mechanical properties of the products. Among recent and current work, prominence has been given to lines of research of immediate interest to the industry, and some important practical achievements are already claimed.

In rolling, much of the research has been, and is being, devoted to the automatic control of the thickness of strip being rolled. The Association holds several patents in this field, and last year the first industrial installation of its 'setting' method of automatic control of strip gauge was put into operation on a reversing cold-strip mill at the Lancashire and Corby Manufacturing Co. by the Davy and United Engineering Co.; several other installations at home and abroad are in hand. Current research is devoted to the operation of 'tandem' mills used, for example, in the manufacture of tinplate and motor-car bodies; a model three-stand mill has been built for the purpose, with some novel features incorporated.

Investigations of the reheating of ingots and billets for forging have led to significant improvements of present practices in heating. For example, cast ingots of high-speed tool steel can now be heated in an hour or less, as against overnight heating hitherto practised. Among results of recent industrial applications of this are a 25 per cent saving of fuel, a 50 per cent reduction of scale loss, and the elimination of decarburization. Attention is now being given to the mechanization of forging and the improvement of the control of forging plant. The 200-ton laboratory press has been fitted with a position-control system developed by the Association whereby forging is made more speedy and accurate.

In wire drawing, an invention by Prof. D. G. Christopherson of a method for inducing hydrodynamic lubrication has been adapted by the Association to conventional soap-powder lubrication. Full-scale trials in wire mills are more than fulfilling expectations, since dies last twice to ten times as long as previously. In another method, the wire is electroplated during drawing with a thin film of lubricant, which is transparent so as to preserve the high finish required for some applications.

Many other investigations are in progress. The stress–strain characteristics of a dozen steels at high temperatures and rapid rates of deformation have been determined for the calculation of rolling loads in hot rolling. Small steel bars are rolled experimentally as part of investigations into the mechanics of the rolling of sections. The causes of stretcher-strain markings and the mechanisms of their suppression by temper rolling, roller and stretch-levelling have been studied and are now understood more completely. The Swift test of the suitability of sheet metal for drawing and pressing has been further developed. The influence of tool geometry on the mechanical properties of finished forgings has been studied. Experimental investigations have been made of die pressure and drawing force, and of the temperatures in the interior of the die at the interface between the die and wire.

Metallurgy

The Metallurgy (General) Division deals essentially with the treatment, properties and uses of iron and steel. A considerable amount of the work is done extra-murally in university and government laboratories, or collaboratively in the works and laboratories of member firms, but specialist teams in the Divisional Laboratory deal with particular aspects of the work.

Theory suggested that stretcher-strain markings on steel sheet, when deep-drawn or pressed, were produced by the diffusion of nitrogen and carbon through the material. Experiments have confirmed the theory, and have shown that nitrogen has a worse effect than carbon. Transformer laminations are usually made of iron containing 3–4 per cent of silicon. Its magnetic properties are seriously affected by small amounts of impurities, particularly nitrogen. Reducing the nitrogen content of very pure silicon-iron from 0·007 to 0·004 per cent saved rather more than 10 per cent of the total losses, and the effects of additions of nitrogen are much the same in commercial material. The strength, energy and mobility of grain boundaries, which control such properties as brittleness, transformations and recrystallization of metals, are being explored by measurements of internal friction. Work is being done to improve the structure of high-speed tool steels.

Fatigue research was undertaken to determine statistically the variation in fatigue properties of wrought material from different ingots and from different parts of the same ingot for two different casts of steel. Statistically significant variations in properties have been found, but these are not thought to be of practical importance. Further work is in hand with a very-high-tensile steel. Increasing importance is being given to the production, in large quantities, of mild steel having a high resistance to brittle fracture. The effect of variations in rolling conditions, such as variation in the finishing temperatures of rolling, rolling schedules, etc., is being studied.

The analytical section provides a service to the whole Association and also undertakes analytical research. Special methods have often to be developed, for example, for the determination of trace elements, or when only very small samples are available. The characteristics of spectrographic source units and the sensitivity and reproducibility of analysis under various arc-like and spark-line conditions have been studied for a large number of elements normally present in steels.

Steel Users

The Steel Users Section of the Association is mainly responsible for answering technical inquiries on the uses of steel, undertaking *ad hoc* and short-term investigations concerning uses of steel and maintaining contact with the smaller member firms of the Association. Typical work concerns the establishment of the optimum heat-treatment procedure for the manufacture of specific products, investigations of obscure difficulties, and advice on matching the performance of components with steel specifications.

Associated Research Councils

The Cutlery Research Council is an autonomous and independently financed co-operative research organization formed in 1951 to work for members of the Sheffield Cutlery Manufacturers' Association. Its work is organized and controlled by the cutlery industry, but its staff are in close and constant collaboration with the British Iron and Steel Research Association, which provides services, background information on steels, and general assistance. At present the main research projects of the Council are: to improve methods for the production of blanks; to study cutting edges; and to study the grinding and polishing processes used in finishing cutlery. There is also a technical inquiry service, which gives confidential technical assistance to individual manufacturers on application.

The File Research Council is another autonomous and independently financed co-operative research organization formed in 1955 to work for members of either the File Trade Association or the File Manufacturers' Association. The unit is controlled by its member firms, but there is close collaboration with the British Iron and Steel Research Association, which provides services, background information on steel and general assistance. In addition to confidential technical inquiry facilities the Council has begun work on the metallurgy of file steels with particular reference to methods of heat treatment and on testing methods for both saw and engineers' files. The shapes of file teeth and methods of producing a desired shape are also being studied.

The Coil Spring Federation Research Organization has only recently taken over laboratory space at Sheffield; it is in the process of being equipped and expects to undertake active research work in the near future.

OBITUARIES

Prof. Walther Kossel

Walther Kossel, who died after a long illness on May 22, was one of Germany's outstanding physicists, both as a theorist and as an experimenter. He was born on January 4, 1888, into a family that included many men distinguished for their learning. In particular, his father, Albrecht Kossel, was a famous physiologist, long professor at Heidelberg. A students' torch-light procession in his honour, on the occasion of his being awarded the Nobel Prize in Physiology and Medicine, was one of the events during the time when Walther was working for his doctorate in Lenard's laboratory at Heidelberg.

After taking his doctorate in 1911, Kossel moved to Munich, where the University and Technische Hochschule numbered many names renowned in the physical sciences: men such as Arnold Sommerfeld, Max von Laue and Jonathan Zenneck, as well as the world-famous Röntgen. In this stimulating atmosphere he produced work of prime importance on the electronic structure of the nuclear atom, which was then in active development. In particular he dealt with the theory of X-ray emission and absorption, explaining for the first time the mechanism of excitation of the different series and the fine structure of the absorption edges in terms of the Bohr atom. Equally important was his work on valency and molecular structure in terms of complete electron groups, work which was fundamental for later developments. Together with Sommerfeld he put forward in 1919 the so-called displacement rule for optical spectra. Thus by the time he was in his early thirties, Kossel was known for basic discoveries in quite different fields of atomic theory. At the same time he learnt with Zenneck the latest developments of high-frequency electric waves and took part, during the First World War, in the development of electronic valves.

In 1921 he went as professor of theoretical physics to Kiel, which had a fine tradition, Lenard and Dieterici having held chairs there. Here he continued his work on valency and published a second edition of his "Valenzkräfte und Röntgenspektren", the title of which summarizes his work so far. In 1927 he gave evidence of his devotion to a new subject in his first work on crystal growth, in which he dealt with simple structures only, but in a way that lies at the basis of much recent work. In 1932 he followed his old Heidelberg friend Ramsauer by being appointed to a chair at the Technische Hochschule at Danzig; this time as professor of experimental physics, evidence of the range of his activities. Among his most important work here was the discovery of the interference effects produced by the characteristic Röntgen rays excited in a single crystal, in the first case a copper single crystal, the so-called Kossel effect, first announced in 1935. He also carried out distinguished research on the interference of electrons. The significance of his work was recognized by the award of the Max Planck Medal in 1944.

At the end of the War in 1945, Kossel escaped with his family from Danzig, leaving practically all his possessions there, and started again. After a troubled time he was in 1947 appointed professor at Tübingen, the charming town in Württemberg which had escaped undamaged from the war. Here he had an excellent laboratory and a most agreeable residence in the Physics Institute. A great variety of work was here accomplished under his inspiring guidance. Results were produced in the field of the diffraction of electrons and of light, electrical discharges in gases and in the subject of crystal structure, for which he made use of large spherical single crystals of metal, of the kind first produced by his old Heidelberg friend Wilhelm Hausser.

In 1953 his life was saddened by the loss of his beloved wife, who had shared all his troubles with never-failing courage and gaiety and who was always ready for work or play, as occasion demanded. He was already suffering from the illness that ultimately caused his death, so that his last years were in many ways clouded. But he was mentally clear and active until the end, and his plans for future work showed his old powers. He lectured by special invitation in Paris, for example, in 1955.

Kossel was a physicist whose work was throughout marked by clarity and imagination. The fundamental concepts for theory or experiment were simple and original, and they were carried out with remarkable thoroughness and closeness of reasoning. He was an excellent exponent and devised striking lecture experiments. Personally he was a man of great uprightness and warm affection, whose public life and family life were alike admirable. His loss will be widely deplored.

E. N. da C. Andrade

Dr. E. M. Lourie

Chemotherapy and tropical medicine have suffered loss by the sudden death on August 11 at Geneva of Dr. Emanuel Mannie Lourie, chief of the Section of Biological Standardization of the World Health Organization. He was born in Johannesburg on February 18, 1904, and studied medicine at University College Hospital, London, qualifying M.B., B.S. in 1928. He took the D.T.M. & H. of the London School of Hygiene and Tropical Medicine in 1930 and the D.P.H. in 1934; and he was elected M.R.C.P. in 1948. After qualifying he worked for various periods in Palestine, at the Liverpool School of Tropical Medicine and at Chicago with Prof. W. H. Taliaferro. In 1934 he returned to the Liverpool School as a Beit Memorial Fellow to work in close association with Prof. Warrington Yorke on the chemotherapy of trypanosomiasis. After the death of Yorke in 1943 Lourie was appointed as the first director of the Department of Chemotherapy of the Liverpool School of Tropical Medicine. During his whole association with the School he was one of its chief scientific ornaments, and in 1945 he was awarded the Chalmers Gold Medal of the Royal Society of Tropical Medicine and Hygiene. In 1948 he left the Liverpool School and after a short period in the Department of Pharmacology at Oxford he joined the World Health Organization, in which his work and his personality were highly appreciated.

Lourie's scientific work covered a wide field; but his main contributions were made in the chemotherapy of tropical infections. In the four years before the Second World War, he and Warrington Yorke discovered the diamidine compounds as a cure for trypanosomiasis and other infections. One of these compounds, pentamidine, was later found to have a prolonged prophylactic action, so that a single intramuscular injection is sufficient to protect against trypanosomiasis for more than six months. This compound has been used prophylactically on a wide scale in Africa and has made a large contribution to the conquest of human sleeping sickness there. Lourie took a major part in developing these compounds, both in Britain and in Africa. In 1943 he discovered that the new antibacterial agent, penicillin, was also very effective in curing mice infected with *Spirochaeta recurrentis*, the organism of relapsing fever. This finding obviously suggested that penicillin would probably be effective also against the organism causing syphilis, and Lourie in collaboration with others showed that this was in fact the case. His important discovery was, however, overshadowed by the simultaneous publications of American workers, and so it did not receive the recognition which was its due.

After the War Lourie showed that the newly discovered antimalarial compound proguanil ('Paludrine') would induce drug-resistance in the malaria parasite of chickens, *P. gallinaceum*. He also studied the melaminyl series of arsenical compounds and promoted the further investigation of these compounds in the field in Africa.

One of Lourie's later contributions to knowledge has only recently been properly appreciated. In 1950 he showed that the acidic compound, suramin, formed complexes with the basic compound pentamidine, such that the toxic action of the two was diminished but the prophylactic action against trypanosomes was greatly prolonged. Recently

Williamson and other workers of the West African Institute for Trypanosomiasis Research have extended this principle to other antitrypanosome compounds, for example, ethidium; compounds of this type will probably be very valuable in controlling the trypanosomiasis of cattle and in opening up for grazing large areas of Africa infested with tsetse flies.

In character Lourie was modest, quiet and reserved; he was a persistent and careful worker and showed great generosity to his junior scientific colleagues. He leaves a wife and one son. His loss will be felt by many friends throughout the world.

F. Hawking

Mr. Llewelyn S. Lloyd

Llewelyn S. Lloyd, who died on August 14, was one of the small band of able Civil Servants Sir Frank Heath brought with him from the Board of Education to help in the foundation in 1916 of the Department of Scientific and Industrial Research. Until his retirement in 1943 Lloyd faithfully served the Department, first as an assistant secretary and later as a principal assistant secretary, and there is no doubt his work contributed very largely to its survival as an efficient organization through the succession of economic blitzes of the years between the Wars. He disarmed the critics by keeping costs low, particularly those of administration, and by encouraging directors to obtain contributions from outside sources towards as many items on their programmes as possible. Though these policies were probably right in the particular circumstances of the time, he was perhaps inclined to carry them too far as the climate for research improved.

Possibly, for one in his position, Lloyd was apt to pay too great attention to administrative details. This, however, made him a most successful trainer of junior staff. To the auxiliary staff he often seemed something of a martinet; but even the most timid registry clerk found, in the end, that his bark was much worse than his bite. Although to his colleagues some of his own letters sometimes appeared too long, his insistence on clear thinking and its expression in forthright English led to his Department achieving a reputation for efficient administration.

The lines Lloyd laid down for dealing with Treasury officials have stood the test of time. "The Treasury," he would say, "can certainly require D.S.I.R. to reduce its demands for money and it must always be satisfied that our estimates are drawn as carefully and closely as possible, but it is not for the Treasury to criticise the scientific aspects of a project or the priority D.S.I.R. attaches to it. These matters have been considered by the Advisory Council whose advice has been accepted by the Lord President."

Lloyd had many interests outside his official work. These included gardening, golf and music. In his later years he was much attracted by the relation between music and science. He embodied his ideas on the subject in a volume entitled "Music and Sound", and spent much time in his retirement in developing them.

Probably few people saw eye to eye with Lloyd all the time; but his was a most endearing personality and those who knew him best count it a privilege to have worked with him. He gave the best years of his life to the Department of Scientific and Industrial Research, which owes him an enduring debt.

O. F. Brown

NEWS and VIEWS

Metallurgical Education in Texas: Prof. E. H. Bucknall

Up to the present, the metallurgical courses offered in the College of Engineering in the University of Texas have been somewhat limited in scope and number, being in the main optional subjects for students in mechanical or chemical engineering. With the recent great influx of industry to Texas and the prospect of intensive developments in the atomic-energy field, an increasing demand is being felt for engineers with a grounding in physical metallurgy, as well as for specialists in this subject. Under the inspiration of Dean W. R. Woolrich, who was for a time scientific attaché at the U.S. Embassy in London, it has been decided to expand the metallurgical content of the undergraduate engineering courses, to institute a master's degree in metallurgy and to sponsor metallurgical research. To carry through this programme, the University has appointed E. H. Bucknall as visiting professor of metallurgical engineering and he will shortly take up his duties at Austin. Prof. Bucknall, who was formerly connected with the National Physical Laboratory and with the Research and Development Laboratories of the Mond Nickel Co., Ltd., has recently returned from India, where he spent three years as director of the National Metallurgical Laboratory and ex-officio director of inspection (metals).

Messrs. Macmillan regret to announce that, as from the issue dated January 5, 1957, the price of *Nature* will be 2s. 6d.

British Iron and Steel Research Association

Mr. C. N. Kington has resigned his post as group manager of the Sheffield Laboratories of the British Iron and Steel Research Association, director of research of the Cutlery Research Council and research superintendent of the File Research Council, on appointment as chief mechanical and electrical engineer of Husband and Co., consulting engineers and architects, of Sheffield, London and Ceylon. Mr. Kington, who is a graduate of the University of Birmingham, received his early training in sound broadcasting and telecommunications. He served throughout the War in the Technical Branch of the Royal Air Force. Dr. J. Pearson, assistant director of the Association, will take charge of the Sheffield Laboratories. At the same time, he will remain head of the Steel-making Division; but he will relinquish control of the Chemistry Department, for which Mr. E. W. Voice, head of the Ironmaking Division, will become responsible. Mr. R. Mayorcas has been appointed deputy head of the Steelmaking Division. Mr. E. O. Oldfield has been appointed senior research officer of the Cutler Research Council in succession to Mr. Kington; and Dr. J. Pearson has been appointed consultant to the File Research Council, with Mr. R. H. Hancock continuing as senior investigator. Mr. J. G. Wistreich, who has been head of the Metal Working Laboratory in the Sheffield Laboratories, will become head of the Mechanical Working Division in succession to Mr. W. C. F. Hessenberg, deputy director of the Association, who is relinquishing control of the Division in order to devote the whole of his time to his other duties. Mr. S. S. Carlisle, head of the Association's South Wales Laboratories, becomes deputy head of the Division.

Biochemical Principles in Pharmacy

PROF. K. BULLOCK, in the chairman's address on September 3 to the British Pharmaceutical Conference, discussed "Biochemical Principles in Pharmacy". His survey covers enzymology, chemotherapy and disinfection, the relationship between dehydration and life processes and the architecture of living cells. He has achieved a valuable synopsis which presents a balanced account of important principles relevant to his subject and to hypotheses which appear promising. The historical approach and his sequences of discovery and thought, whereby knowledge has grown, are stimulating—the divergencies from one's own sequences can be intriguing. It is an unavoidable penalty to which even excellent surveys must submit that the illustration of a principle may over-simplify the explanation of cause and effect without consideration of every alternative. For example, the phenomena whereby bacteria can utilize a substrate which at first they could not attack, by enzyme induction, is real enough; but in some instances the phenomena can occur where the enzyme involved is constitutively present but inactive because of coenzyme deficiency. The presence of metal ions—including the monovalent ions—may also affect the activity of some of these enzymes, as the recent symposium of the Biochemical Society shows. Does the reference to the known relationship between the bactericidal properties of the sulphonamides and their antagonism to paraminobenzoic acid exclude other possibilities for sulphonamide action? These comments cannot detract from the value of this extensive and profitable review. When Prof. Bullock dealt with dehydration and life processes, he was in his own chosen field. Does he move almost imperceptively from a position of acquiescence in faith to one of faith in experience?

Engineering Studies in the U.S.S.R.

A BRITISH engineering delegation is to visit the U.S.S.R. this month to study engineering education and training. The nine members of the group were nominated by the Joint Committee of the Institutions of Civil, Mechanical and Electrical Engineers and the visit will take place under the auspices of the Soviet Relations Committee of the British Council. A return visit to the United Kingdom by a group of Soviet experts is under consideration. The group will leave London by air on September 16, returning probably on September 28. The programme in the U.S.S.R. will include visits to higher technical education establishments in Moscow and Leningrad. The group will be led by Prof. E. Giffen, professor of civil and mechanical engineering, Queen Mary College, University of London. Other members are: Mr. W. K. Brasher, secretary of the Institution of Electrical Engineers; Dr. B. N. Cole, Department of Mechanical Engineering, University of Birmingham; Mr. H. E. Dance, H.M. Inspector of Schools (Technical Branch); Dr. H. L. Haslegrave, principal of Loughborough College of Technology; Mr. G. S. C. Lucas, director and chief electrical engineer, British Thomson-Houston Co., Ltd., Rugby; Mr. P. E. Sleight, head of the Civil Engineering Department, Brighton Technical College; Mr. E. G. Sterland, principal, Apprentices' School, Bristol Aeroplane Company; Prof. A. S. T. Thomson, Department of Mechanical, Civil and Chemical Engineering, Royal Technical College, Glasgow.

Supply and Training of Teachers for Technical Colleges

A COMMITTEE, nominated by the chairman of the National Advisory Council on the Training and Supply of Teachers and the chairman of the National Advisory Council on Education for Industry and Commerce, has been set up to advise the Minister of Education urgently upon the recruitment and training of teachers for technical colleges. Its terms of reference are: "To consider in the light of the White Paper on Technical Education (Cmd. 9703) the supply and training of full-time and part-time teachers for technical colleges, and to make recommendations", and it is constituted as follows: Dr. Willis Jackson (*chairman*), director of research and education, Metropolitan-Vickers Electrical Co., Ltd.; Councillor R. McKinnon Wood (*vice-chairman*), London County Council; Dr. F. Briers, principal, Norwich City College and Art School; Sir Hugh Chance, chairman, West Midlands Regional Advisory Council for Technical, Commercial and Art Education; Alderman C. B. Jones, Yorkshire Council for Further Education; Mr. D. R. Mackintosh, Shell Petroleum Co., Ltd.; Miss Anne Shaw, director, The Anne Shaw Organization; Mr. J. G. Docherty, principal, North-Western Polytechnic, London; Mr. A. E. Evans, technical adviser, Association of Teachers in Technical Institutions; Mr. H. Wyn Jones, secretary, Welsh Joint Education Committee; Prof. R. A. C. Oliver, Sarah Fielden professor of education in the University of Manchester; Mr. E. W. Woodhead, Chief Education Officer, Kent; Mr. A. Maclennan, principal, Training College for Technical Teachers, Huddersfield.

Birlec Ltd. Apprentice Training Centre, Birmingham

BIRLEC LTD., furnace manufacturers, of Birmingham, have been training apprentices in their works for some considerable time; but in view of the company's plan for expansion and the need to ensure a continuing supply of trained men of the highest calibre, a new apprentice scheme has been launched and a new Apprentice Training Centre has been built specially. Four full-time instructors have been appointed, two of whom have held lecturing posts in the Birmingham College of Technology and the National Foundry College, Wolverhampton, respectively. It is anticipated that the new scheme will cost approximately £20,000 a year. The new Centre is accommodated in single-story buildings and occupies about 10,000 sq. ft. of floor space, with workshop, drawing office and lecture room facilities.

Two main courses are provided, 'technical' and 'craft', each of not less than five years duration. All trainees spend their first year on preliminary courses in the Centre to find the direction in which their abilities lie, and to give them an insight into the fundamentals of engineering with particular reference to those branches with which the Birlec Co. is concerned. After this probationary period, training is then continued in appropriate departments for the remainder of the five-year period, selected apprentices returning to the Centre for advanced instruction at an intermediate stage. All trainees are also required to attend suitable courses at local technical colleges for at least one day a week. Selected apprentices may be offered the opportunity of attending sandwich courses of four to five years at a college of technology, leading to qualification for membership of the appropriate professional engineering institution. There are at present about sixty apprentices in the firm, some forty of whom were recruited this year.

Swiss Society for Natural Sciences

THE 136th annual meeting of the Swiss Society for Natural Sciences will be held during September 22–24 at Basle. The opening address by the president, Prof. A. Werthemann of Basle, is on "Pathology of Embryonic Development". Dr. A. Wettstein of Basle will speak on "Aldosteron and Other Suprarenal Hormones", Prof. J. Piveteau of the Sorbonne on "Recent Progress in Human Palæontology in France", and Prof. E. Hadorn of Zurich on "Hereditary Constitution and the Formation of Characteristics". At a joint symposium, the Societies for Medical Biology and for Genetics will discuss "Malformation of the Gonads and Genetic Sex". The Society for the History of Medicine and Science will hold a symposium on "Medicine at Basle in the Baroque Period". A public session of the Swiss Community for Educational and Scientific Research Films will be addressed by Dr. G. Wolf, of Göttingen, and biological and medical films will be shown.

The meeting will be held in fifteen main sections. Foreign contributors include C. E. Tilley (Mineralogy and Petrography) and P. Tschumi (Zoology and Entomology) of Cambridge, and several from the East European Universities of Poznan (Anthropology), Budapest and Greifswald (Chemistry). In the Geophysical, Meteorological and Astronomical Section, Prof. J. Lugeon of Zurich will report on "The World Comparison of Radiosondes at Payern", and on "Measurements of the Electric Potential Gradient and the Conductivity of the Air by Radiosondes", and J. Häfelin and R. Lotmar of Zurich on the "Determination of Weather Effects on Skin Permeability (Experiments on Rabbits)". Prof. H. Hadwiger of Bern speaks in the Mathematical Section on "Selected Problems of Combinatory Geometry in Euclidian and Spherical Space". The Section for Logic and Philosophy lists four prominent speakers, Profs. Paul Bernays of Zurich ("From Syntax to Philosophy of Science"), Emil Walther of Zurich ("The Problem of Direct, Phenomenological Thought"), Felix Fiala of Neuchâtel ("Methodological Notes on Formalism") and François Bonnet of Geneva ("Irreversibility, Disorder and Chance"). The Society announces as the new topic for the one thousand francs Schläfli Prize (open only to candidates of Swiss nationality, closing date April 1, 1959): "Researches on the Distribution of Polyploid Plant Species in Switzerland".

Zoological Nomenclature

As from January 20, 1957, the International Commission on Zoological Nomenclature will start voting on the following cases involving the possible use of its plenary powers for the purposes specified against each case, full details of which have already been published (*Bull. Zool. Nom.*, 12, Pts. 4 and 5; July 20, 1956): (1) *depurator* Linnaeus, 1758 (*Cancer*), interpretation of, by neotype designated for (cl. Crustacea, order Decapoda); (2) *Cherax* (emend. of *Cheraps*) Erichson, 1846, and *Palinurus* (emend. of *Pallinurus*) Weber, 1795, validation (cl. Crustacea, order Decapoda); (3) *ferox* Gmelin, 1771 (*Accipiter*), suppression (cl. Aves); (4) *Maja* Lamarck, 1801, validation of and designation of type species for (cl. Crustacea, order Decapoda); (5) *Sao* Barrande, 1846, and *Ellipsocephalus* (emend. of *Elleipsocephalus*) Zenker, 1833, validation (cl. Crustacea, order Stomatopoda); (6) *Heteralocha* Cabanis, [1851], validation (cl. Aves); (7) *Acrodytes* Fitzinger, 1843, *venulosa* Laurenti, 1768 (*Rana*) and *tibiatrix* Laurenti, 1768 (*Hyla*), suppression (cl. Amphibia, order Salientia); (8) *Palaeophonus* (emend. of *Palaeophoneus*) Lindström and Thorell, 1884, validation (cl. Arachnida); (9) *Actinocrinus gilbertsoni* Phillips, 1836, interpretation of, by neotype (cl. Crinoidea). Comments should be sent as soon as possible to the secretary to the Commission, Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

Museum of Applied Science of Victoria, Melbourne: Report for 1954–55

THE annual report of the Museum of Applied Science of Victoria, Melbourne, for the year ended June 30, 1955 (pp. 17; 1956), records major steps in the general building programme which should go a long way to ease congestion. A special exhibit of a demonstration model of the Lurgi plant for the production of gas from the extensive brown-coal deposits in the Latrobe valley has been installed in the main entrance to the Museum. This semi-diagrammatic model was constructed by the staff of the Museum and shows each unit in section, starting with the high-pressure reaction unit and proceeding to the final gas-purification tower from which it will be piped to Melbourne. Each stage of the process is explained by a panel of text, which is illuminated in sequence by an automatic time-switch.

Extension to the Rowett Research Institute

THROUGH the generosity of the Wellcome Trust, the Rowett Research Institute, Aberdeen, is now able to go ahead with the erection of a building to house the special equipment for research in animal nutrition which the Rockefeller Foundation was prepared to grant to the Institute if a suitable building were put up for it. These awards by the Wellcome Trust and the Rockefeller Foundation—up to £5,000 and £4,900 respectively—will now permit the staff of the Institute to isolate and prepare, in larger quantities than can at present be achieved in its laboratories, microbial, plant and animal constituents for further identification, analysis and *in vivo* testing.

The Library Association

THE annual conference of the Library Association will be held at Folkestone during September 18–21, under the presidency of Mr. Edward Sydney. The programme includes papers on international librarianship (Dr. H. Coblans, head of the Information Service of the European Organization for Nuclear Research), libraries in colleges of technology (Mr. L. L. Ardern, librarian of the College of Technology, Manchester), libraries of the learned societies (Mr. K. D. C. Vernon, librarian of the Royal Institution), and on "Science, Humanism and Libraries" (Mr. D. J. Foskett, librarian and information officer of the Metal Box Co., Ltd.). There will also be an exhibition of books and library equipment. Further information can be obtained from the Secretary, Library Association, Chaucer House, Malet Place, London, W.C.1.

Ministry of Agriculture Postgraduate Awards

THE Ministry of Agriculture, Fisheries and Food has awarded the following postgraduate research and training scholarships in agricultural economics, agricultural engineering, husbandry and farm management, tenable in the first instance at the university or institute shown for periods of up to two years: *Agricultural Economics:* M. J. Dorling (Oxford), B. B. Perkins (Manchester), Miss P. M. Prosser (Reading), P. F. Romney (University College of Wales, Aberystwyth); *Agricultural Engineering:* T. H. E. Harrison, S. Moore and M. R. Potter (King's College, Newcastle upon Tyne); *Husbandry:* D. M. Allen (Nottingham), G. W. Arnold (Wye College), W. J. M. Black (King's College, Newcastle upon Tyne), M. W. Case (Long Ashton Research Station, Bristol), D. C. Dalton (University College of North Wales, Bangor), J. L. Hammerton (University College of Wales, Aberystwyth), B. Roscoe (King's College, Newcastle upon Tyne), P. J. M. Sale (Reading), D. B. J. Thompson (Reading), L. J. White (Wye College); *Farm Management:* D. Hardy (Reading), P. M. Harris (Leeds), D. Wilman (Leeds).

As part of the Conditional Aid Programme, the Ministry of Agriculture, Fisheries and Food announces that the following postgraduate scholarships have been awarded in farm management, tenable at the universities shown for a period of one year: B. J. F. James (Oxford), G. J. Tyler (London).

The Nature Conservancy: Awards for 1956

THE Nature Conservancy announces the following awards of research studentships for postgraduate training in ecology, tenable for periods up to three years at the universities shown: *Botany:* C. D. K. Cook (Cambridge); K. A. Kershaw (University College of North Wales, Bangor); A. Pettet (Southampton); Miss P. J. Warwick (Birmingham). *Zoology:* B. C. Clarke (Oxford); O. W. Heal (Durham); Miss J. Kear (Cambridge); G. H. Manley (Oxford). *Geology:* M. P. Kerney (London).

Physical Society: Awards and Officers for 1956–57

THE Council of the Physical Society has made the following awards for the year 1957: *Guthrie Lecture,* Prof. H. C. Urey; *Charles Chree Medal,* Sir Edward Bullard; *Duddell Medal,* Dr. C. E. Wynn-Williams; *Charles Vernon Boys Prize,* Dr. L. Essen.

The following have been elected officers of the Society for the session 1956–57: *President,* Prof. N. F. Mott; *Vice-Presidents,* Dr. A. B. Wood, Prof. S. Devons, Prof. F. Llewellyn Jones, Prof. H. Jones; *New Members of Council,* Dr. V. E. Cosslett, Dr. D. Gabor, Mr. E. S. Shire; *Honorary Secretaries,* Dr. C. G. Wynne and Dr. H. H. Hopkins; *Honorary Foreign Secretary,* Prof. E. N. da C. Andrade; *Honorary Treasurer,* Mr. A. J. Philpot; *Honorary Librarian,* Dr. R. W. B. Pearse.

Announcements

MR. A. L. BACHARACH has retired after more than thirty-six years on the staff of the Glaxo organization. His services in a consultative capacity are being retained for continued editorial work on "The Glaxo Volume" and on papers written by members of the Company's scientific staff for publication in scientific and medical journals.

THE Ministry of Supply announces the following appointments at the Royal Aircraft Establishment, Farnborough: Mr. E. C. Cornford, to be head of the Guided Weapons Department; Mr. D. J. Lyons, to be senior superintendent, Ballistic Missiles Division of the Guided Weapons Department; and Mr. P. A. Hufton, to be senior superintendent, Supersonics Division of the Aerodynamics Department. Mr. Cornford, Mr. Lyons and Mr. Hufton have all been promoted to the grade of deputy chief scientific officer on taking up their new appointments.

THE Institution of Electrical Engineers is arranging a convention on "Ferrites", which will be held in London at the Institution during October 29–November 2. The topics to be discussed will be the theory, preparation and properties of ferrites; microwave applications; square-loop applications; radio and television applications; and carrier-frequency applications. More than fifty papers will be read. Delegates will be attending from France, Germany, Holland, Sweden, the United States and, it is hoped, from the U.S.S.R. Further information can be obtained from the Secretary of the Institution at Savoy Place, London, W.C.2.

THE Clay Minerals Group of the Mineralogical Society is holding a meeting in London on November 2, at which "Clay Minerals and Soil Mechanics" will be discussed. Civil engineers and geologists will be particularly welcome at this meeting. Offers of papers and inquiries should be sent to the secretary of the Group, Dr. R. C. Mackenzie, at the Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen.

THIS year's Convention of Chemical Sciences of the Société de Chimie Industrielle will take place in Paris during November 18–December 3 and will include a number of meetings (to be held during the dates indicated): an international congress of industrial chemistry (November 18–24); a European congress on corrosion (November 18–24 and on December 3); a European conference on chemical engineering (November 22–24); the Paris technical meetings of the Society (November 26–30); and a chemical, rubber and plastics exhibition (November 22–December 3). The first two will be at the Maison de la Chimie, and the others in the Palais des Congrès and the Parc des Expositions at the Porte de Versailles. Further information can be obtained from the Société de Chimie Industrielle, 28 rue Saint-Dominique, Paris 7e.

MESSRS. Oliver and Boyd have written pointing out that the price of "Physiology and Biochemistry of Lactation", by Dr. S. J. Folley, is incorrectly given in their advertisement in *Nature*, September 1, supp. p. iv, as 63*s.*; it should read 18*s.* 6*d.*

ERRATUM. In the communication on "Relationship between the Amine Contents of the Two Adrenal Glands of the Cat" by Drs. K. R. Butterworth and M. Mann in *Nature* of August 18, p. 363, legend to Fig. 1, for "hatched" read "clear".

THE ROCKEFELLER FOUNDATION

GRANTS made by the Rockefeller Foundation for the second quarter, 1956, have recently been published. The following are some examples of work being supported by the Foundation to a total of nearly seven million dollars.

For the first time a high-powered nuclear reactor will be equipped with a special opening to provide streams of energy solely for medical and biological research. The design of the new 1,000 kilowatt nuclear reactor now under construction by the Massachusetts Institute of Technology is being altered to include an extra port on one of its faces. The Rockefeller Foundation has appropriated 250,000 dollars for the addition of this special medical facility.

Research on low-cost, protein-rich foods to improve the diets of food-deficient populations will be the object of two projects which the Rockefeller Foundation will assist during the next three years. A grant of 250,000 dollars to the U.S. National Research Council will be used for studying the nutritional value of proteins in products available in under-developed countries. The London School of Hygiene and Tropical Medicine in England will use a grant of £17,000 for research on the biological value of proteins in tropical foodstuffs.

The Rockefeller Foundation has renewed its aid to the Rural University of the State of Minas Gerais, Brazil, with a grant of 200,000 dollars for the further development of its School of Agriculture and Agricultural Experiment Station during the next three years.

To support a programme of research on plant and animal genetics, under the leadership of Profs. H. J. Muller, T. M. Sonneborn and R. E. Cleland, the Rockefeller Foundation has made an outright grant of 350,000 dollars to the University of Indiana—an important centre for genetics research. The grant will enable Prof. Muller to continue his research on the modifications of individual genes. Prof. Sonneborn has developed an almost uniquely personal field of study by utilizing the rapidly reproducing *Paramecium* to show that inheritable characters depend not only upon chromosomal structures within the cell nucleus, but also upon elements which may be found in the cytoplasm and which behave in part like genes and in part like viruses. This discovery may have an important bearing on research in the heredity of mammalian cancer. Prof. Cleland, applying the genetic theory to the evolution of plants, has shown how a stable recombination of genes can be selected by environmental pressures to produce entirely new species. The work of the Indiana group is also being supported by the Atomic Energy Commission, the National Science Foundation and the American Cancer Society.

A 260,000-dollar grant will be used over the next three years for purchasing basic research equipment for two newly created science institutes at the University of Copenhagen. New buildings now under construction will house the institutes. The Institute of Biology's new building will permit expansion of existing departments of the Faculty of Science and the creation of new ones. The Marshall Plan, the Carlsberg Foundation, industry and the Danish State have combined to furnish funds for construction. The Institute of Experimental Medicine and Surgery, where research is concentrated in areas of medicine between the purely basic sciences and clinical fields, will also have new quarters. Danish insurance companies contributed a major share of the building fund, which was augmented by a government grant of land and money. Danish botanists, who have made significant contributions in the study and cultivation of arctic plants, will also have a new cold house where meteorological conditions in Greenland can be approximated. A portion of the current Rockefeller grant will be matched by funds from Danish sources for construction of the cold house as an adjunct to the Institute of Biology.

Of the many research laboratories which are making rapid advances towards an understanding of the nature of viruses, one of the most prominent is that of Prof. Barry Commoner at Washington University, St. Louis, Missouri. For general support of Prof. Commoner's research programme, the Rockefeller Foundation has appropriated 165,000 dollars, available during the next four years.

The collaborative biological and biochemical researches in genetics, cytology and evolution at the Johns Hopkins University, an integrated programme of the Department of Biology and the McCollum-Pratt Institute, will be supported by an outright Rockefeller Foundation grant of 100,000 dollars. Prof. W. D. McElroy, director of the Institute and newly appointed chairman of the Department of Biology, will lead the consolidated research programme. Prof. B. H. Willier, distinguished embryologist and recently retired chairman of the Department of Biology, will continue to be active in research.

Support for an unusual biological research programme in a liberal arts college setting will be continued by an outright Foundation grant of 100,000 dollars to Amherst College. Inaugurated at Amherst in 1934, the research activity is concentrated in genetics and embryology. Under the leadership of Prof. Harold H. Plough, chairman of the Department of Biology, the work has resulted in a substantial increase in the number of students entering on careers in the biological and medical sciences.

The molecular mechanisms by which fungicides produce their effects in controlling plant diseases will be studied intensively in a new research project at the Boyce-Thompson Institute for Plant Research, Yonkers, New York, directed by Dr. George E. McNew. A grant of 105,000 dollars from the Rockefeller Foundation will give partial support to this project over a five-year period.

To further the development of agriculture in Puerto Rico, the Bureau of the Budget of the Commonwealth will review the organization and administration of insular agricultural agencies through a survey to be supervised by Dr. José Noguera, director of the bureau. The Rockefeller Foundation has appropriated 85,000 dollars to the Commonwealth of Puerto Rico to assist with the expenses of the survey during the next two years.

As part of its world-wide programme to investigate and assist investigations of arthropod-borne virus diseases, the Rockefeller Foundation has appropriated about 73,800 dollars, available over the next five years, to the University of Malaya, Singapore, to aid further research on Japanese *B* encephalitis and other virus diseases by the Department of Bacteriology.

In support of basic research on the nature of viruses, the major effort of the Walter and Eliza Hall Institute of Medical Research, Australia, an eight-year grant of 60,000 dollars has been made by the Foundation. The programme dealing with various phases of virus research is under the supervision of Sir Macfarlane Burnet, a leading investigator of the biology of viruses and director of the Institute, whose studies on the genetics of influenza viruses have resulted in a series of highly important findings.

Two Rockefeller Foundation grants totalling 80,000 dollars have been made to Balwant Rajput College in India to aid rural students and to promote the development of an agricultural training centre on a new 436-acre experimental farm. An outright grant of 10,000 dollars will provide a scholarship and revolving loan fund for local students. The second Rockefeller appropriation of 70,000 dollars will be used over a three-year period for building and equipping classrooms, laboratories and a library at the new site of the College of Agriculture. The College, affiliated with Agra University, is successfully bridging the gap between agricultural theory and local practice in its efforts to improve rural life.

The biochemical research of Dr. J. H. Quastel, director of the Institute of Special Research in Cell Metabolism in Montreal, will be aided by a new five-year grant of about 56,650 dollars to McGill University. The work of Dr. Quastel has been supported by the Foundation since 1936, when he held a medical sciences fellowship. Dr. Quastel will conduct a new series of laboratory studies of the effects on the processes of cell metabolism of tranquillizing and other drugs used in the treatment of mental illness. One of the first biochemists to apply modern biochemical methods to study of the brain, he will return to this field of his earlier interest in view of important recent clinical findings on drug therapy and psychosis. His early discovery of the mechanism of action of barbiturates in depressing brain metabolism formed the basis of much of the later work done in this area. More recently, Dr. Quastel has been working with intermediate carbohydrate metabolism, certain aspects of protein synthesis, and the relation between proteins and fats.

A national survey of the attitudes of newspaper and magazine readers toward science and science news, sponsored by the U.S. National Association of Science Writers, will be financed by a 70,000 dollars grant from the Rockefeller Foundation. Available over an 18-month period, the grant will make possible a 2,000-person poll to be conducted by the Survey Research Centre of the University of Michigan. The grant will be administered by New York University.

An interdisciplinary research project on the relationship of cultural patterns and personality, at the Nagoya University, Japan, will be financed in part by a 60,000-dollar grant, available over a three-year period, from the Rockefeller Foundation. Prof. Tsuneo Muramatsu, professor of neuropsychiatry at Nagoya Medical School, will direct the study.

A research and training programme in Middle Eastern economic and cultural geography will be established by the University of Durham, to enable a group of scholars to study in the Middle East. In support of the project during a five-year period, the Rockefeller Foundation has appropriated £16,925 to provide a series of postdoctoral and junior fellowships. Prof. W. B. Fisher, head of the Department of Geography, will direct the programme.

The University of Cambridge will inaugurate a research programme in experimental animal psychology with partial aid from a Rockefeller Foundation grant of £15,000, available during the next five years. The new programme will be developed as the primary research interest in the Department of Experimental Psychology under the direction of Prof. Oliver Zangwill.

A new method of analysing changes in the birth-rate, the cohort system, will be used for assessing the main factors influencing population growth in the United States by the Scripps Foundation for Research in Population Problems at Miami University, Oxford, Ohio. Dr. P. K. Whelpton, director, will conduct a two-year study with Rockefeller Foundation support of 40,000 dollars. The cohort system uses groups, or 'cohorts', of women born in the same year and follows their child-bearing experience during the course of their reproductive life. Analyses based upon the cohort tables together with other data will be used by the Scripps Foundation group to prepare new and more accurate estimates of future population growth in the United States.

The deterioration of stored grain, a food problem of world-wide importance, and the basic chemical changes occurring in seed under varying storage conditions, will be studied by a group at the Kansas State College led by Dr. Max Milner, a distinguished cereal chemist. The three-year project will be financed by a 36,000-dollar grant.

Research equipment for a new laboratory of biochemistry at the University of Ferrara, Italy, will be provided over the next three years by a grant of 40,000 dollars from the Rockefeller Foundation. The new laboratory is under the direction of Prof. Enzo Boeri.

The School of Medicine of the University of Wisconsin will institute a research programme in medical genetics with partial support from a three-year, 25,000-dollar grant from the Rockefeller Foundation. Dr. Newton Morton, formerly a member of the Atomic Bomb Casualty Commission in Japan, will direct the programme.

Among other awards are: a total of 950,000 dollars to three Indian medical schools; a total of 365,000 dollars to three Brazilian medical schools; a grant of 290,000 dollars to a Japanese medical school; a grant of 250,000 dollars in support of the programme in international student exchange of the Institute of International Education, New York; a grant of 111,600 dollars to the American Library Association for the maintenance of an overseas library planning and development office.

Other grants have been awarded to institutes and individuals in the United States, Canada, Latin American countries, most European countries, Iraq, India, Pakistan, Thailand, Australia, Japan and the Philippines.

One hundred and thirty-one fellowships were awarded by the Foundation during the second quarter of 1956. These were distributed as follows: agriculture, 31; biological and medical research, 17; humanities, 31; medical education and public health, 41; social sciences, 11.

GRASSLAND AND THE FEEDING OF LIVESTOCK

THE Nutrition Society held a meeting in Reading on July 20 which took the form of a symposium on "Grassland and the Feeding of Livestock", a subject of major importance in relation to the improvement both of the efficiency of animal production and of human nutritional status. Prof. H. D. Kay (Shinfield) was in the chair.

The first contributor was Dr. William Davies (Hurley). In an introductory paper he laid emphasis on the unstable nature of the grassland sward, ever changing in one direction or another in response to environmental changes. Following the destruction by man of the primeval forests which at one time covered the greater part of the present cultivable area of Great Britain and his subsequent agricultural efforts, several types of grassland of different botanical composition and of differing agricultural value developed. These can be conveniently divided into six major types, from the ryegrass–white clover pasture at the better end to the *Molinia-Nardus* pasture at the poorer. Far from stable, the poorer types can be improved under suitable management—including fertilizer treatment and grazing—or the better types can deteriorate when improperly managed. In one recorded trial, for example, fertilizer (calcium, nitrogen, phosphorus and potassium) treatment of a mainly *Molinia* hill pasture not only completely changed the botanical composition of the sward in a few years but also gave nearly ten times the yield of herbage (measured in lb. of dry weight per acre per year). Even grazing alone (without added fertilizer) of such a pasture more than doubled the yield of dry matter per acre in less than ten years. One of the effects of the fertilizer treatment was to bring in species, such as rough-stalked meadow grass and white clover, which were not present at all in the original sward. Good pasture management and knowledgeable fertilizer treatment not only give greatly increased yields of consumable grass, but also extend the normal grazing season into the autumn and spring.

Prof. W. Holmes (Wye) discussed the so-called law of diminishing returns in relation to the application of increasing quantities of nitrogenous fertilizers to crops and grass. For cereal and root crops the response curve is logarithmic; thus, it has been found that for cereals each successive fertilizer dressing of 28 lb. of nitrogen per acre increases (on the average) the yield by 53 per cent of the previous increment. For leafy crops such as kale, the response is much greater, 28 lb. of nitrogen per acre increasing the yield by 78 per cent of the previous increment. For grassland the percentage response is greater still; given suitable temperatures and water supply, it is almost linear up to an application of 300 lb. of nitrogen per acre. Application of nitrogen also increases the efficiency with which water is used by the growing grass. A further factor arises when grass is grazed—namely, the return of nitrogen and other grass nutrients in the form of dung and urine; in effect, some of the fertilizer nitrogen is used more than once. Response to nitrogen treatment depends on climate, water supply, season and frequency of application. The situation is complicated since, owing to its content of legume, the normal clover–grass sward derives directly or indirectly substantial quantities of nitrogen from the clover (of the order of 150–250 lb. of nitrogen per acre per year). Application of small amounts of fertilizer nitrogen in spring is very harmful to the clover and gives, therefore, poor total response; but heavy dressings give good responses in terms of total yields per acre, since grass is greatly stimulated though the clover is suppressed.

The capacity of grass to respond to large amounts of nitrogen is outstanding, and from the point of view of farm economics, very cheap cattle food may be produced by the skilful use of nitrogenous fertilizers. Provided there is also mastery of the technique of the utilization of grass by cattle, the results in animal production may be very profitable. This latter aspect was dealt with by Mr. A. S. Barker (London), who, in his paper on fertilizer nitrogen and milk production from grassland, emphasized the great importance of skilled management in making optimum use for grazing animals of the increased production of grass. Taking one year with another, the joint effect of fertilizer plus management can be measured in a dairy herd by the output of milk per cow per year or per acre of grassland per year. Given appropriate grassland and livestock management, it has been shown in a series of trials on farms that the application of increasing quantities of nitrogenous fertilizer from 23 lb. of nitrogen per acre in steps of 23 lb. up to 115 lb. will increase the output of utilized feed at the rate of about 2–3 cwt. of 'starch equivalent' per acre for each increment of 23 lb. of nitrogen, and that at a practically linear rate. Mr. Barker stated that, from the profit-and-loss point of view, at prices current during the past two years, £1 spent on fertilizer has given a considerably greater return in milk production than £1 spent on purchased food.

Mr. W. F. Raymond (Hurley) spoke on the measurement of pasture output. Most systems of pasture evaluation take little account of two of the main characteristics of pasture output—namely, that it is made up of a number of harvests in any one year, and that management in one year affects yields and persistence in subsequent years. Optimum management methods vary with different pastures. The total annual yield is of less importance practically than the distribution of that yield between different months of the year, while such herbage characters as persistence, palatability and winter greenness are also of major importance in relation to the evaluation of any particular sward for stock. Pasture investigation requires measurement of effective output from a pasture over a relatively short period; some techniques which have apparently been valid for assessing output over a whole grazing season are inadequate when applied to short grazing periods. As a yardstick, live-weight gains, at least over short periods, are not very helpful; milk production is a rather more sensitive reflexion of pasture output than live-weight gains, but is even more dependent on management. Two methods of assessing pasture intake are being investigated, involving herbage cutting or fæcal measurements with an indigestible tracer such as chromic oxide for determining the quantity of fæces voided, and analysis of the amount of lignin in the fæces to determine the digestibility of the herbage, with the aid of a 'fæcal index' based on indoor experiments on digestibility.

Dr. M. J. Head and Mr. J. A. F. Rook (Shinfield) discussed certain effects of spring grass on rumen digestion and the metabolism of the dairy cow, particularly in relation to hypomagnesæmia. Heavy dressings of nitrogenous fertilizer in early spring produce a rapid growth of succulent herbage containing a high percentage of crude protein. If this herbage is grazed by dairy cows as their sole diet, it provides an unbalanced ration containing excess of protein equivalent. The effect of the sudden change from the winter ration to such an unbalanced diet in the spring is not infrequently to induce severe hypomagnesæmia and 'tetany'.

Rumen fermentation of such spring herbage has been shown to lead to increased production of ammonia; the ammonia is absorbed from the rumen into the blood stream and can be demonstrated in the portal vein and sometimes in the peripheral blood. This production of ammonia in the rumen can be depressed by feeding starch. Ammonia in the circulating blood may be toxic in relatively low concentrations.

Hypomagnesæmia in the cow in spring is due in part to the low availability to the animal of the magnesium in spring herbage, and in part to the relatively low daily intake of magnesium in the grass diet in comparison with the intake from winter feed. The hypomagnesæmia is most severe in those cows with the highest levels of ammonia in the blood. If the ammonia concentration in the rumen of a cow is artificially raised, the magnesium-level in the blood is depressed. On the other hand, low level of magnesium in the blood induced by feeding young spring grass may be raised again by feeding maize starch, which at the same time causes a drastic reduction in ammonia-levels in the rumen.

The final paper in this symposium, by Dr. W. A. McGillivray (Palmerston North, New Zealand) and Dr. S. Y. Thompson (Shinfield), was concerned with the influence of pasture on the vitamin A and carotene in the milk of cows. Calculation shows that, in the average human diet in Britain, cows' milk contributes about 20 per cent of the daily requirements of vitamin A. Three factors influence the vitamin A content of cows' milk, as follows: stage of lactation—colostrum and very early lactation milk are richer in both carotene and vitamin A than milk secreted during the rest of the lactation period; hormonal influences—the thyroid plays a part in carotene metabolism in the cow; and feed of the cow—the major factor. The cow converts carotene inefficiently into vitamin A. Intake of carotene is, however, probably quite sufficient on pasture to produce butter with high vitamin A potency; but on a winter diet this potency diminishes markedly. In New Zealand, where cows—predominantly Jerseys—are fed outdoors on pasture throughout the year, a uniformly high vitamin A potency in milk fat might be expected. In fact, the potency depends in large part on the botanical composition of the herbage, less carotene being absorbed and utilized on a pasture containing much clover than on one containing little clover. The tocopherol content of milk fat is likewise decreased on a high-clover pasture. There are probably two forms of carotene in blood plasma, one which contributes little to milk-fat-carotene levels and is associated with vitamin A alcohol, and the other which is present on a carotene-containing diet and is associated with vitamin A ester and dietary fat in the chylomicrons, taken up directly by the mammary gland to contribute to the synthesis of milk fat.

Quickly growing, 'improved' pasture produces a number of metabolic disturbances in sheep and in cows in New Zealand. Muscular dystrophy is found in young sheep (though there is adequate tocopherol in the pasture). There seems to be an anti-vitamin D factor in pasture, producing rickets in young lambs. Bloat in cows is a serious problem in New Zealand—drenching the cows with oil appears to be an effective treatment. Facial eczema in sheep, associated with lush pasture, also causes serious losses in some years; its cause is not yet understood.

Each paper in the symposium was followed by a short but lively discussion; from these discussions it is clear that two of the present urgent needs in relation to the feeding of farm livestock on pasture are: first, more knowledge of those constituents of rapidly growing herbage which at times upset the metabolic balance of grazing ruminants; and second, how such upsets can be most conveniently prevented in practice on the ordinary farm, without diminishing the advantages of modern methods for improving the efficiency of grassland production.

H. D. Kay

THE 1956 CAMBRIDGE SUMMER SCHOOL IN PHYSICAL CHEMISTRY

THE rate at which modern science advances continues to increase, and most scientists, though confining their activities within narrow channels, find themselves incapable of synchronizing with the acceleration. One way of contending with this situation is by means of the refresher course, where a small number of lecturers who have paid special attention to certain selected subjects give brief reviews on recent developments, stressing general theoretical principles rather than detailed experimental technicalities. With this object in mind, the Department of Physical Chemistry of the University of Cambridge has arranged summer schools, at intervals of three years, since the end of the Second World War.

This year's summer school, held during August 18–25, began with an inaugural lecture on Saturday night by the head of the Department, Prof. R. G. W. Norrish, who outlined briefly the history of the University of Cambridge and in particular of the origin and growth of its scientific departments. Prof. Norrish is particularly well qualified for such a lecture, being a Cambridge man in every sense of the word; he was born in the City, and, before entering the University, was educated at the Perse School, the ancient hall of which is now one of the most attractive features of his Department. The lecture, though full of fact, was interspersed with adequate humour, and helped to create an atmosphere of welcome to the 116 visitors who attended the school. The first real mingling of the visitors among themselves and with many Cambridge dons began in a garden party held on Sunday in the pleasant grounds of Sidney Sussex College.

The scientific course, which started on August 20, consisted of a course of fourteen lectures devoted to two broad topics, both of which are rapidly developing, namely, the applications of spectroscopy to chemical problems and the application of intermolecular force theory to the study of fluids. The first lecture was given by Prof. H. C. Longuet-Higgins on the nature of intermolecular forces and the properties of imperfect gases. Direct electrostatic, induction and dispersion forces play a part in determining intermolecular potential energies, and must be supplemented by repulsive forces, which predominate when molecules get very close together. This led naturally to a treatment of the liquid state of matter, which was given by Dr. E. A. Moelwyn-Hughes. Theories of free space, moving holes and anharmonic oscillators were reviewed, and new data presented on the heat capacities of liquids at constant volume. Both these lecturers spoke later, and from different angles, on current theories of solutions of non-electrolytes. Longuet-Higgins showed how the thermodynamic properties of regular solutions could be derived on a statistical basis, while making a small number of assumptions concerning the form and relative magnitude of the three interaction-energy terms. Dr. Moelwyn-Hughes explained how the theories of van Laar, Hildebrand and Scatchard can be derived in terms of a simple model of a solution and of the partition function to which it leads. Dr. J. N. Agar gave two lectures on selected topics dealing with solutions of electrolytes. He dealt with heats and entropies of hydration of ions, with the limitations of Born's theory, and with a new hypothesis on solvation which can explain the magnitude of the ionic activity coefficient in quite strong solutions. Mr. R. P. Bell, of Oxford, one of the visiting lecturers, spoke on the hydrogen bond and the very wide range of phenomena connected therewith. The hydrogen bond deserves to be treated as distinct from other types of bonds. Our knowledge in this field began with the study of the interaction of two carboxylic acids, and now extends to the interpretation of the so-called anomalous properties of hydroxylic liquids and solutions.

The discussion on modern developments in spectroscopy was opened by Mrs. D. M. Agar, who gave an account of infra-red and Raman spectra, with their application to such problems as rotational isomerism and forbidden transitions. There followed a lecture by Prof. W. C. Price, of King's College, London, the second visiting lecturer, on observations made in the visible and ultra-violet regions. Electronic spectra and ionization potentials of polyatomic molecules are now telling us much about the pattern of electrons in molecules and of their energy states, just as atomic spectra long ago provided Rutherford and Bohr with a picture of electronic arrangements and energies in free atoms. The nature of the chromophoric group in the normal and excited states of the molecule can be understood in terms of a fairly simple free-electron theory. Among the more spectacular spectroscopic developments of the past decade are those associated with the production of free radicals under the influence of an intense flash and with their characterization during their transient existence. The first lecture on this subject was delivered by Prof. Norrish, who first described in general terms the methods of kinetic spectroscopy and their application to isothermal reactions of free radicals. Among the many problems which have been tackled by the new method are the rates of combination of free atoms, the mechanism of the interaction of carbon monoxide with various gases and the conversion of the vibrational energy of the oxygen molecule into energies of other forms. The marked advances made in radio-frequency spectroscopy, and the related topics of nuclear magnetic resonance, were treated in two lectures by Dr. T. M. Sugden. Moments of inertia, intermolecular distances, valency angles and dipole moments are among the molecular properties which can be measured by the radio-frequency method. Dr. Sugden's third lecture dealt with the applications of spectroscopy to the study of flames. The concentration of free electrons in flames can now be determined fairly accurately, and the results can be applied to estimate the energy required to dissociate molecules into radicals, and complex radicals into simpler ones. Values of the bond energies thus found have been confirmed by other means. The course concluded with a lecture by Prof. Norrish on the study of explosions by means of kinetic spectroscopy. The mechanisms of the reaction between hydrogen and oxygen and of the oxidation of hydrocarbons have been studied by the new method, which has served also to throw light on the nature of the knock and anti-knock effects met with in combustion.

Each lecture was followed by discussion, and the two morning lectures at 9.30 and 11.15 were separated by an interval when discussions continued over coffee. One cannot attend lectures and take part in discussions the whole day through, and the organizers of the summer school had wisely provided amenities to fill in the leisure hours. Most of the men attending the school were housed in Corpus Christi College and Pembroke College, and the five women were accommodated in the Corpus Christi College Hostel. There was a reception in the Guildhall on August 21, when scientists forgot that they were scientists and relaxed in dancing or sipping wine under the influence of pleasant music. Mr. Hugh J. McLean gave an organ recital in the chapel of King's College on August 23, when the visitors had an opportunity of listening to some of the fugues and voluntaries of Orlando Gibbons, a chorister of the College in 1596, and of Bach, Mozart, Franck and Willan. Those who attended the school were also entertained by Prof. and Mrs. Norrish at their home and by the senior members of his staff at evening parties given at their homes or in their colleges. On August 24 the school and a number of guests dined in the hall of Pembroke College under the presidency of Prof. Norrish, with Sir Owen Wansbrough-Jones, chief scientist of the Ministry of Supply, as principal guest.

Most of those attending the school were research workers or those engaged in teaching physical chemistry. Fifty-four came from industrial research establishments, which included Bakelite, British Celanese, British Rayon, Bush, Boake Roberts, Courtaulds, Distillers, Dow Chemical Co., Esso, J. Lyons, Imperial Chemical Industries, Laporte, Monsanto Chemicals, Metropolitan-Vickers, Philips (Eindhoven), Pilkington's, Rolls-Royce and Shell. There were thirty-two academic scientists from the Universities of Belfast, Berlin, Columbia, Copenhagen, Delft, Geneva, Glasgow, Göttingen, Hong Kong, Leyden, Liège, London, Marburg, Moscow, Prague, Southampton, Texas, Tokyo, Virginia and Warsaw. There were nine representatives of research and development establishments of the various Ministries of the Crown and six teachers from public and grammar schools.

It is almost impossible to over-rate the importance of the contacts established in such a gathering. The great number of questions put to the lecturers in private conversations proved that the topics dealt with were of immediate interest and value. The lecturers themselves have also learnt much of what is happening in wide fields of research enterprise outside their own university. Ideas were freely exchanged and, like the poet's joy, improved on being poured from one vessel to another. There was a refreshing frankness in all the school's deliberations, and there was a free trade of thought.

No account of the physical chemistry summer school at Cambridge would be complete without some reference to the happy human relationships which were established, and in many cases strengthened, between academic research workers and industrial research workers, and between British scientists and foreign scientists. Politicians have yet to learn that scientists are men who are kindly disposed towards one another, have a common faith and interest in their subject and desire nothing more than freedom to study Nature and to subjugate her to the benefit of mankind. A gathering of this kind can be lightly described as just another conference, conducted with evident pleasure, and not unprofitably. On the other hand, its consequences are incalculable. To bring industrial and academic research workers together is a vital step in furthering the national economy. To bring foreign scientists from all over the world—including that part which lies beyond the 'iron curtain'—into harmonious contact with British scientists is to increase the volume of international goodwill, in an age when that commodity is none too abundant, and when the contribution of the scientists to it is paramount. E. A. MOELWYN-HUGHES

GLAZED FROST IN ENGLAND OF JANUARY 1940

GLAZED frost, the phenomenon of rain or drizzle falling on a frozen earth and covering everything with a layer of clear ice, is not of very frequent occurrence in Britain and, when it does occur, it is usually short-lived and quickly followed by an influx of air warm enough to melt the ice. In the United States it is sufficiently common and severe to be called an ice storm. The main economic effects are severe disturbance of transport by the very slippery roads and paths and destruction of overhead telegraph and power lines. The precipitation falls from clouds at a temperature above freezing point through a low-lying layer of air at a temperature below freezing point. The supercooled droplets freeze on striking the ground, trees, telegraph wires and so on, forming a coating of clear slippery ice. Usually the phenomenon is transitory because it is produced by the fairly fast-moving warm front or warm occlusion of a winter depression.

During January 25–February 4, 1940, however, as is described by Dr. C. E. P. Brooks and Mr. C. K. M. Douglas in Geophysical Memoir No. 98 of the Meteorological Office, entitled "Glazed Frost of January 1940"*, intense persistent glazed frost formed over much of England south of a line from the Humber to the Mersey except East Anglia. It was especially intense along a wide belt from North Wales to Kent. The ice formed cylinders up to 2½ in. in diameter on telegraph wires, twigs, etc., and a coating an inch thick on the ground. Telegraph poles and trees collapsed in large numbers under the weight of the ice. The memoir contains some vivid photographs of the ice which the authors describe as probably unequalled, certainly in at least a century, for extent and persistence in Great Britain.

The meteorological circumstances producing the ice are fully described. At the time there was an anticyclone over Scandinavia and a depression south-west of Iceland. Between these systems a very cold south-easterly wind blew across most of the British Isles with temperatures between 25° and 30° F. inland. Two warm fronts moved successively early in the period from the south-west across Ireland, south-west England and Wales and then oscillated slowly backwards and forwards over the mouth of the Channel and south-west England, bringing the rain which fell through the cold surface air to produce the glazed frost. Finally, on February 3, the warm air swept northwards, displacing the cold south-easterly current over the country and melting all the ice. The chief technical meteorological interest lies in the motion of the fronts, which over a considerable period departed widely from that given by the components of geostrophic wind normal to them.

The differences were abnormally large. One warm front over south-west England on January 28, which should, on the geostrophic basis, have moved at the rate of 15 m.p.h. to the north-east, moved at 5 m.p.h. south-west. The differences between actual and geostrophic wind are too large to be accounted for by accelerations associated with pressure changes, and the best suggestion is that of a departure caused by turbulent friction in the frontal zone in which the wind changed rapidly in direction. This friction introduces a term in the hydrodynamic equations proportional to the coefficient of turbulence, multiplying the second differential coefficient with respect to height of the wind component parallel to the front. It is shown in the memoir that this would have the right order of magnitude.

THE BUKIDNON OF MINDANAO

PROF. FAY-COOPER COLE'S recent field-work monograph on the people of one of the larger islands of the Philippines, entitled "The Bukidnon of Mindanao"*, is an unusual publication. Had it been written by an anthropologist as a result of recent field-work, it is doubtful whether there would have been any justification for having it published. But the field-work dates from 1910, and the author is a professor of anthropology (emeritus) writing in 1956. The situation has its possibilities, and on commencing to read the monograph one wonders whether the author will succeed in producing a work of contemporary interest on foundations that are left over from a different period. The answer is, unfortunately, no.

It would, of course, be unfair to take the author to task for not having had 1956 in mind in 1910; but it is obviously true that he has been unable to decide what to do with the material himself, and, as a result, the book is concerned with everything in general, but nothing in particular. There are good illustrations of material objects, houses and dress, all of which are interesting, but within the scope of a hundred-odd pages the text rushes through chapters with such diverse titles as "Making a Living"; "The Life Cycle, Social and Political Organization"; "The Spirit World"; "The Ceremonies"; "Music and Dancing"; "Celestial Bodies"; "Stories and Legends".

Prof. Cole seems to have had no concern for kinship, at least in 1910—which is a pity; for the Bukidnon appear to have a system of bilateral kinship on the Iban pattern, but there are scarcely any asides in that direction. The remarks on marriage are more tantalizing than illuminating, and social and political organization—including such headings as crime and law (four paragraphs) and slavery (two paragraphs)—merits only ten pages.

* Air Ministry: Meteorological Office. Geophysical Memoir No. 98: Glazed Frost of January 1940. By Dr. C. E. P. Brooks and C. K. M. Douglas. Pp. 40+10 plates. (M.O. 584f) (London: H.M.S.O., 1956.) 7s. 6d. net.

* *Fieldiana*: Anthropology. Vol. 46. "The Bukidnon of Mindanao". By Prof. Fay-Cooper Cole. Pp. 140. (Chicago: Chicago Natural History Museum, 1956.) 4 dollars.

It is not that the author has no interest in the problems of social anthropology; for example, he reports the notable phenomenon—recorded also in other areas—that as the "aggressive intervention" (*sic*) of the authorities (in this case the American Governor) increased in the daily life of the people, and as they were forcefully moved into "model villages", there was a "withdrawal into the old ways in religion". With the decline of the political importance of the local headmen, the influence of the "mediums" and their ceremonies became more powerful "to the extent that they dominated the social and religious life" of the Bukidnon. But all this is merely stated and not followed up. There are, instead, descriptions of ceremonies concerned with ritual healing and with the fertility of the crops, and there are discussions on the concepts of the supernatural. However, the author seems to have worked through interpreters, and what with the unclear social background and without the backbone of a theory to give the material some coherence, these pages remain unrewarding.

The conclusion strikes a different vein. For, when the author is left with two pages, he reveals that he had in mind all the time "the attempt to account for the peopling of Central and Southern Mindanao": this aim is certainly not disclosed earlier on, nor is it pursued with much vigour. NUR YALMAN

VOLTA RIVER PROJECT IN THE GOLD COAST

THE report of the preparatory commission on the Volta River Project set up in 1953 by the United Kingdom and Gold Coast Governments was published on July 27 as a non-parliamentary paper, and the Secretary of State for the Colonies, Mr. A. T. Lennox-Boyd, said in a written answer in the House of Commons on that day that the report provides evidence of an extremely thorough examination of all the problems to be solved in a project of this magnitude. The main conclusions of the commission are that the project is technically sound and could be carried out successfully; it is not capable of significant improvement from an economic point of view, but the greatest return would be derived by achieving maximum production as soon as possible. The commission further concludes that the project should be competitive in relation to other schemes, provided that the time-table of construction is observed, a sound policy adopted in the employment and provision of living conditions for the labour force, economic stability maintained in the Gold Coast, and that the aluminium companies are satisfied that the internal cost of operating the smelter would be acceptable. The report also considers such factors as the co-ordination of the future development plans of the Gold Coast Government, the maintenance of adequate administrative and technical services, and the level of future world demand for aluminium and future developments in the generation of power from nuclear energy.

As a result of its investigations, the commission considers that the scheme, based on two stages of aluminium production, would cost £184·9 million (with a capacity of 120,000 tons a year), rising to a total of £231·3 million (with a capacity of 210,000 tons a year) compared with the estimates of £116 million and £144 million in 1952 but including also certain additional work. The commission suggests that it would be prudent to allow for a further increase of 40–50 per cent so as to obtain a realistic appreciation of the finances that might be required for the project, which would take about eight years to bring to production. This increase should not make the project less attractive provided world prices move upwards at roughly the same rate. The United Kingdom and the Gold Coast Governments and the aluminium companies have each re-affirmed their interest in the project, though none of them is yet committed to participation. They have agreed that, because of the substantial increase in the estimated capital cost, it is necessary to review both the framework and the method of finance; as the next step, the International Bank is being asked to make a general assessment of the project and to indicate the extent to which it would be willing, in principle, to participate if the two Governments and the aluminium companies reached agreement on the framework.

POLLEN CHEMISTRY

R. LUNDÉN, with the citation of some eighty-one references, has given a useful résumé of the literature of pollen chemistry (*Grana Palynologica*, 1, No. 2, 3; 1956). The protein and amino-acid content of different pollen grains has long been of special interest and practical importance, on one hand, to apiarists in search of a pollen substitute in the rearing of bees, and, on the other, to medical investigators interested in the active principle in pollen allergy.

With the development of partition chromatography, considerable advances are now being made in ascertaining both qualitative and quantitative facts regarding the amino-acid content of grains; indeed, all the common amino-acids have now been found to be present in pollens, either bound to protein or in the free state, though some important deficiencies have been reported. As the carbohydrate content of pollen grains is considered to be of less importance from the point of view of bee nutrition, this aspect of pollen chemistry has received rather less attention; but analytical data have been given for the starch, cellulose, pentosan and reducing sugar contents of the pollen of a number of species. Lipides have also been examined.

Studies of the vitamins and hormones of pollen grains have shown that, in general, they are rich in the vitamins of the B group but low in fat-soluble vitamins; some quantitative information relating to a considerable number of vitamins is now available for several species. The evidence indicates pollen to be an exceptionally good source of water-soluble vitamins, for example, of thiamine, riboflavin, pantothenic acid, nicotinic acid and ascorbic acid. Œstrogenic substances have been detected in certain pollens, and also plant growth regulating substances. Pollen enzyme chemistry likewise promises to be a particularly rich field for research. Reference is also made to the pigments, which are chiefly flavonols and carotenoids, and to the inorganic and various miscellaneous constituents.

A VIRUS RESEMBLING RUSSIAN SPRING–SUMMER ENCEPHALITIS VIRUS FROM AN IXODID TICK IN MALAYA

By Dr. C. E. GORDON SMITH
Division of Virus Research and Medical Zoology, Institute for Medical Research, Kuala Lumpur, Malaya

A VIRUS (*TP*21) serologically resembling that of Russian spring–summer encephalitis has been isolated from a pool of hard ticks, *Ixodes granulatus* Supino, from forest rats caught near Kuala Lumpur. The probable importance of this finding is two-fold. First, the distribution of viruses resembling Russian spring–summer encephalitis may be wider than was previously known. Russian spring–summer encephalitis, transmitted apparently by *I. persulcatus*, occurs in widespread areas of the U.S.S.R.[1], Czechoslovakia, Slovenia and Austria[2]. The virus cannot be distinguished from that of louping ill[2], which is an encephalomyelitis mostly of sheep, but occasionally of man, transmitted by *I. ricinus* in Scotland. Russian spring–summer encephalitis in Europe and North Asia has apparently a widespread reservoir mainly in rodents and is only occasionally transmitted to man. The only obvious common factor between these areas and Malaya is the presence of *Ixodes* species, which suggests the possibility that *Ixodes* species in many parts of the world may be the vectors of Russian spring–summer encephalitis or antigenically related viruses, some if not all of which may be capable of causing disease in man. Secondly, although *I. granulatus* has not yet been recorded biting man in Malaya, it has a wide host-range, and, as planters and troops are frequently bitten by ticks, we should be alert to recognize human disease caused by this virus.

The relevant technical details are as follows: twenty-four female and one male *I. granulatus* from one *Rattus mülleri validus* (Miller) and one *R. sabanus vociferans* (Miller) were ground up and treated with antibiotics and by high-speed centrifugation. Intracerebral inoculation into day-old suckling mice (*DDM* strain) caused paralysis on the fifth day after inoculation. Passage of bacteriologically sterile brain material from these caused paralysis in adult mice on the fifth day, and in sucklings on the third day. Re-isolation in adult mice from the tick suspension was successful. Using adult mice, one hour incubation of serum–virus mixtures at 37° C. and intracerebral inoculation of ten mice per 10-fold dilution of virus, *TP*21 was tested by neutralization test against antisera to Russian spring–summer encephalitis (I am indebted to Dr. W. L. Pond for this antiserum), Japanese encephalitis, and dengue-1 viruses, of which the last two have been isolated in Malaya. The Russian spring–summer encephalitis antiserum used was the same serum pool as was used by Pond *et al.*[2,3] in their studies of Russian spring–summer encephalitis and related viruses. The latter was suspected because of the high pathogenicity of *TP*21 for adult mice, its lethality by intraperitoneal route, and because it came from *Ixodes* ticks. *VR*4609 and *VR*4610 were sera of two wild-caught *R. rajah surifer* (Miller) which had hæmagglutinin-inhibiting antibody to *TP*21. Clearly (Table 1) there was significant neutralization only by Russian spring–summer encephalitis and the *R. rajah* sera. As no other virus has so far been described with such a close antigenic relationship to Russian spring–summer encephalitis, *TP*21 must be closely related to it if not identical. The neutralizing antibodies in the two *R. rajah* probably indicate natural infection with *TP*21.

Table 1. IDENTIFICATION OF *TP*21 BY NEUTRALIZATION TEST IN MICE VERSUS SPECIFIC IMMUNE ANTISERA

Antisera	*LD*50 titre (negative log) after incubation of virus–serum mixtures	Neutralizing index	Homologous titre of antiserum
Russian spring–summer encephalitis	4·1	790	6,300
Japanese encephalitis	6·9	1	2,500
Dengue-1	6·6	3	250
*VR*4609	4·0	1,000	
*VR*4610	4·0	1,000	
Normal rabbit } controls	7·1 } 7·0		
Normal mouse } controls	6·9		

Table 2. *p*H AND TEMPERATURE CHARACTERISTICS OF FRESHLY PREPARED *TP*21 HÆMAGGLUTININ

agent, which is inhibited by immune sera. However, a hæmagglutinin was prepared from *TP*21 by the method of Chanock and Sabin[5], and its *p*H and temperature characteristics when freshly prepared are shown in Table 2. Third-passage material gave a titre of 1/200,000 at *p*H 6·5 and 4° C. Using this system and acetone-extracted sera[3], a variety of sera were tested for hæmagglutinin-inhibiting antibodies to *TP*21 and Japanese encephalitis (Table 3). Six sera, all from forest ground-rats (*R. sabanus*, *R. rajah*, and *R. mülleri*), were positive only against *TP*21, but a proportion of the human and domestic animal sera which had antibody to Japanese encephalitis also had antibody to *TP*21—this probably indicates cross-reaction between *TP*21 and Japanese encephalitis, as all these sera had higher titres versus the latter than *TP*21. None of the nine pairs of acute- and convalescent-phase sera from cases of pyrexia of unknown origin, nor of the thirty-four sera received for heterophile antibody tests, showed evidence suggestive of previous *TP*21 infection.

*TP*21 was also tested by Dr. B. L. Elisberg of the U.S. Army Medical Research Unit stationed at the Institute for Medical Research, Kuala Lumpur, in a hæmagglutinin-inhibition test against hyperimmune mouse sera prepared by the method of Casals and Brown[6] and his results are shown in Table 4. These results confirm that *TP*21 is antigenically related to Japanese encephalitis and the dengue viruses (that is, it belongs to Casals' *B* group of viruses[6]), but that its behaviour differs from each of them.

*TP*21 inoculated subcutaneously into two macaque monkeys caused fever between the tenth and fifteenth day in one; similar inoculations into albino rats, and wild-caught *R. bowersi*, had no detectable effect. One of two guinea pigs inoculated intracerebrally died, but virus could not be found in its tissues; two inoculated intraperitoneally were unaffected. Adult mice were only moderately susceptible by intraperitoneal inoculation—only four out of six were killed by 10^6 intracerebral *LD*50 doses.

The implication of this very limited study is that infections with *TP*21 may be common and probably often symptomless in forest rats, and that *I. granulatus*, which is common and widespread on ground- and tree-living small mammals in the Malaysian forests, extending northwards to India, may be a vector. Neutralizing antibodies to Russian spring–summer encephalitis virus were found in a few individuals from north-west India by Smithburn *et al.*[7], and work by Pond and his colleagues of the U.S. Army Medical Research Unit (to be published) suggests that such antibodies may also occur in Malaya.

This preliminary report is submitted because, owing to the known laboratory hazards of Russian spring–summer encephalitis virus, work with *TP*21 has been suspended until its identity has been established by a reference laboratory.

POSSIBLE CATION-CARRIER SUBSTANCES IN BLOOD

By A. K. SOLOMON, FABIAN LIONETTI* and PETER F. CURRAN

Biophysical Laboratory, Harvard Medical School, Boston 15, Mass.

THE existence of carrier molecules responsible for the transport of specific ions across cellular membranes has long been postulated, but no substances with the necessary chemical characteristics to fill the role have yet been recognized in biological material. As a consequence, the combination of alkali cations with molecules that are found in living matter is of particular importance to the problem of transport of ions across cellular membranes. Lipide binding of cations has been studied by Christensen and Hastings[1], Folch[2], and Baer, Buchnea and Newcombe[3]. Pyridoxal has been suggested as a carrier by Christensen[4], and the relevance of polyphosphate cation-binding to the carrier problem has been put forward by Steinbach[5]. In the case of the red cell, Solomon[6] has put forward the hypothesis that the complex of sodium and potassium ions with carrier, or carriers, should be lipide-soluble, non-dissociable in lipide, but dissociable in water solution. Thus the cation would be carried through the lipide portion of the membrane as part of a soluble carrier complex.

Human blood and plasma have both served as starting materials. Samples of whole blood were incubated at 37° C. for periods of one hour or more with potassium-42, using the techniques previously described[6]. At the close of the incubation, the blood was frozen and dried under vacuum. 0·5 gm. aliquots of the dried material were then extracted for 15 min.

Table 1. EXTRACTION OF POTASSIUM FROM BLOOD BY VARIOUS SOLVENTS

Solvent	Potassium extracted (m.mole/l. blood)
Diethyl ether	0·003
Benzene	0·004
Chloroform	0·009
Hot 2 : 1 chloroform–methanol	0·429

by shaking with 10 ml. of each of a variety of organic solvents, including chloroform, a hot 2 : 1 mixture of chloroform–methanol (Folch *et al.*[7] have shown that chloroform–methanol is effective in removing lipide from brain tissue, in which it is found in association with proteins), acetone, benzene, diethyl ether, *iso*-propyl ether, and petroleum ether. It can be seen from Table 1 that the chloroform–methanol mixture extracted much more potassium from blood than benzene, ether and chloroform, the behaviour of which was typical of the other solvents studied.

It was necessary to rule out the possibility that the results in Table 1 could be ascribed to the solubility of the inorganic salts of potassium-42 directly in the chloroform–methanol mixture. For this purpose, an additional step was added to the procedure. The filtered chloroform–methanol extract was evaporated to dryness. The dry material was then taken up in chloroform (which had been dried over calcium chloride), filtered, transferred to a counting planchet and dried once more. The potassium content in the final chloroform solution was calculated as millmoles potassium in chloroform solution per litre of material extracted. From Table 1 it can be seen that chloroform by itself extracts only a negligible quantity of potassium-42 from blood. To confirm this point, the usual inorganic buffer solution used in potassium transport studies (ref. 6, Table 1), which simulates the ionic composition of plasma, was dried and subjected to the extraction procedure described above. The potassium uptake (uptake is used in the special sense of cation solubility in chloroform) was 0·0008 m.mole/l. buffer, which is to be compared to values of 0·532 m.mole/l. blood, and 0·221 m.mole/l. plasma when blood and plasma were extracted under the same conditions. From these results it was concluded that a material capable of carrying cations into non-polar solvents, such as chloroform, could be extracted from plasma and blood.

The uptake of potassium by plasma extracts was compared with that of sodium. The potassium ion concentration in plasma was raised to an average of 11·9 m.moles/l. plasma by the addition of the potassium-42; the sodium concentration was 144·0 m.moles/l. plasma. In ten experiments, the average potassium uptake was 2·51 ± 0·62 μmoles/gm. dried plasma; and in six experiments, the average sodium uptake was 11·28 ± 2·24 μmoles/gm. dried plasma. If the uptake is directly proportional to plasma cation concentration, it would be expected that the sodium uptake would be 12·1 times greater than the potassium. The fact that the observed uptake was only 4·5 times greater suggests that the extracted material discriminates between these two cations, potassium being taken up in preference to sodium. The difference in uptake between the cations is expressed in terms of a potassium/sodium competition factor which is defined as (K uptake/Na uptake)/([K]/[Na]) and is equal to 2·7 in this case. If there are saturation effects, a more complex expression will be required.

Experiments were next carried out to see whether the chloroform-soluble material would give up the extracted cation to water. For this purpose, a volume of chloroform extract was shaken with an equal volume of water for 10 min. At the end of this period, 31 per cent of the activity was found in the water solution. The water solution was then shaken again for 10 min. with an equal volume of fresh chloroform, and no potassium-42 was taken up by the chloroform. Thus the material initially responsible for taking potassium ions into the chloroform solution is no longer present in the water phase, and has apparently dissociated, releasing its potassium to the water phase.

Studies were also initiated to determine the extent to which purified lipides might possess the power to combine selectively with sodium and potassium ions. Lipide samples (for which we are indebted to Drs. Manfred L. Karnovsky, Jordi Folch-Pi, Gerhardt Schmidt and James Garvin) were emulsified with buffer solution (sodium chloride and potassium chloride concentrations modified as shown in Table 2) and incubated separately with sodium-24 and potassium-42 ions. The results of these experiments are presented in Table 2. It will be seen that sphingomyelin, phosphatidyl-serine and acetal phosphatide showed characteristic uptakes of sodium and potassium, potassium being taken up preferentially (see Table 2, col. 6). Cholesterol, which has no phosphate or other charged groups, was ineffective in taking potassium and sodium into solution.

Table 2. UPTAKE OF POTASSIUM AND SODIUM IN CHLOROFORM EXTRACTS OF PURIFIED LIPIDES

Lipide	Concentration (m.mole/l.)		Uptake m.mole/m.mole lipide		K/Na competition factor
	Potassium	Sodium	Potassium	Sodium	
Phosphatidyl-serine	4·28	132·8	0·664	1·50	14·2
Sphingomyelin	4·64	132·8	0·645	2·57	7·5
Acetal phosphatide	4·28	132·8	0·386	1·40	8·9
Cholesterol	2·4	64·0	0·005	0·02	6·7

The problem of cation binding has been approached in the present study specifically with the intention of finding a material suitable for transporting cations across the red-cell membrane, and thus of giving support to the carrier theory of ion transport. In this respect, it now appears that a heterogeneous material can be extracted from blood that has the requisite characteristics, namely: (1) it can discriminate between sodium and potassium ions, preference being given to the latter; (2) it is soluble in lipide solvents; and (3) it dissociates in water. It seems likely that the material is lipide in character and possibly contains phosphatides. Whether the material plays a part in cation transport has yet to be established, and experiments covering this aspect of the problem are now in progress.

The present studies have been supported in part by the Atomic Energy Commission. We wish to thank Drs. F. R. N. Gurd, Oscar Hechter, M. L. Karnovsky and F. M. Snell for many stimulating and informative discussions during the course of these experiments.

Observation of Magnetic Domains in Electron Shadow Photographs

During a study of the magnetic effects produced on a fine electron beam by an unmagnetized single crystal of hexagonal cobalt, an effect was found which shows the existence of domains in a particularly vivid manner.

A small aperture of 12μ close to the crystal surface is used to limit the electron beam of a conventional electron diffraction apparatus. This aperture produces, in addition to the main beam, a diffuse electron beam which gives a magnified shadow photograph of the crystal on the photographic plate (Fig. 1). The electron beam is almost parallel to the prism face of the crystal, the direction of the beam being nearly parallel to the hexagonal axis. The horizontal edge of the crystal, appearing in the photograph as a succession of small cusps, is normal to the hexagonal axis and forms part of the prism face. This face is nearly normal to the plane of the photograph. The main beam strikes the crystal surface and does not appear in the photograph.

The explanation of these cusps appears to lie in the action on the electrons of the magnetic leakage field near the surface of the cobalt. It is known[1] that at room temperature the domains in hexagonal cobalt have a preferred axis parallel to the hexagonal axis, that the leakage field is very strong close to the hexagonal face (of the order of 10,000 oersteds)[2] and that it dies off to relatively small values at about 40μ [3]. In an investigation of the fields at an edge of the hexagonal face of a cobalt crystal, Marton, Simpson and Lachenbruch[4] find a value of 100 oersteds at about 40μ.

Using the main beam from the aperture as a probe, the magnetic fields leading to the formation of the cusps were investigated. If the effects on the edge of the hexagonal face of the cobalt crystal are studied with electrons of energy 46 keV., it is found that the cusps are formed from electrons passing at a distance between 70μ to 120μ from the edge, where the average value of the magnetic field is of the order of 100 oersteds. Those electrons which pass closer to the edge are deflected by larger amounts and form part of the general background.

The cusp shape must evidently follow from the character of the multipole field produced by oppositely magnetized domains. In order to explain in a simple manner the formation of the cusps at the edge of the hexagonal face, we take a cross-section through the crystal parallel to the hexagonal axis. This cross-section showing the magnetic domains, and the associated leakage field in this plane, are represented diagrammatically in Fig. 2. We first consider the effect of this field on a parallel electron beam of rectangular cross-section, indicated by the shaded area, which cuts the plane of the figure at a certain average distance from the edge. The deflexions of the electrons in the beam on passing through various parts of the field have been indicated by arrows. These deflexions are shown again in the top diagram, which also shows the resultant effect on the beam, that is, the formation of the cusps. In particular, it will be seen that the distance between successive cusp tips (*a*–*b*, *b*–*c*) is equal to the sum of the widths (*D*) of neighbouring domains of opposite polarity; this sum ($\bar{L}$) we will term 'domain spacing'. Instead of the parallel beam, we can now consider a part of the divergent beam produced by the small aperture, this part having the same cross-section as the parallel beam. Similar cusps will be produced, which will appear highly magnified if photographed at a distance which is large compared with the distance between the aperture and the edge of the crystal.

We next consider the case in which a beam, of the same cross-section as before, is approximately parallel to a prism face and in the direction of the hexagonal axis (as in Fig. 1). The leakage field responsible for the formation of the cusps in this case is produced by the same domains as in the previous case. We consider the field in a plane situated close to the edge and at right-angles to the plane of Fig. 2, if this is taken to be the prism face; it has approximately the same form as the field represented in this figure. A similar analysis again shows that the electron beam is distorted into a succession of cusps. The cusps are observed in both cases discussed, and in other cases in which the beam is not parallel to the hexagonal axis. The illustration (Fig. 1) was chosen because it shows in addition a corner of the crystal.

Measurements of 'domain spacing' have been made in the two cases mentioned above. The magnitude of the 'domain spacing' varies from 40μ to 240μ, the most frequent value lying between 100μ and 160μ. Values of the 'domain spacing' found from published photographs of Bitter figures on the prism face of hexagonal cobalt[1] vary from 40μ to 170μ, which are similar to those found in our experiments.

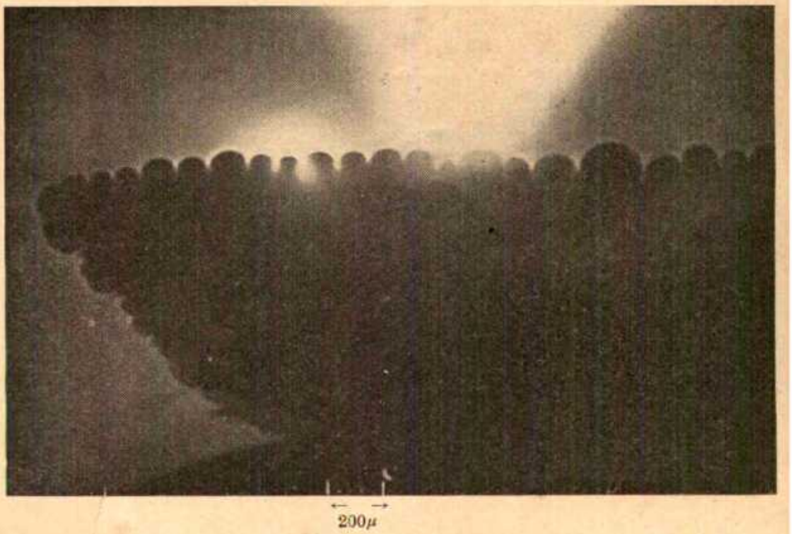

Fig. 1. Shadow photograph of an unmagnetized crystal of hexagonal cobalt, showing domain effects

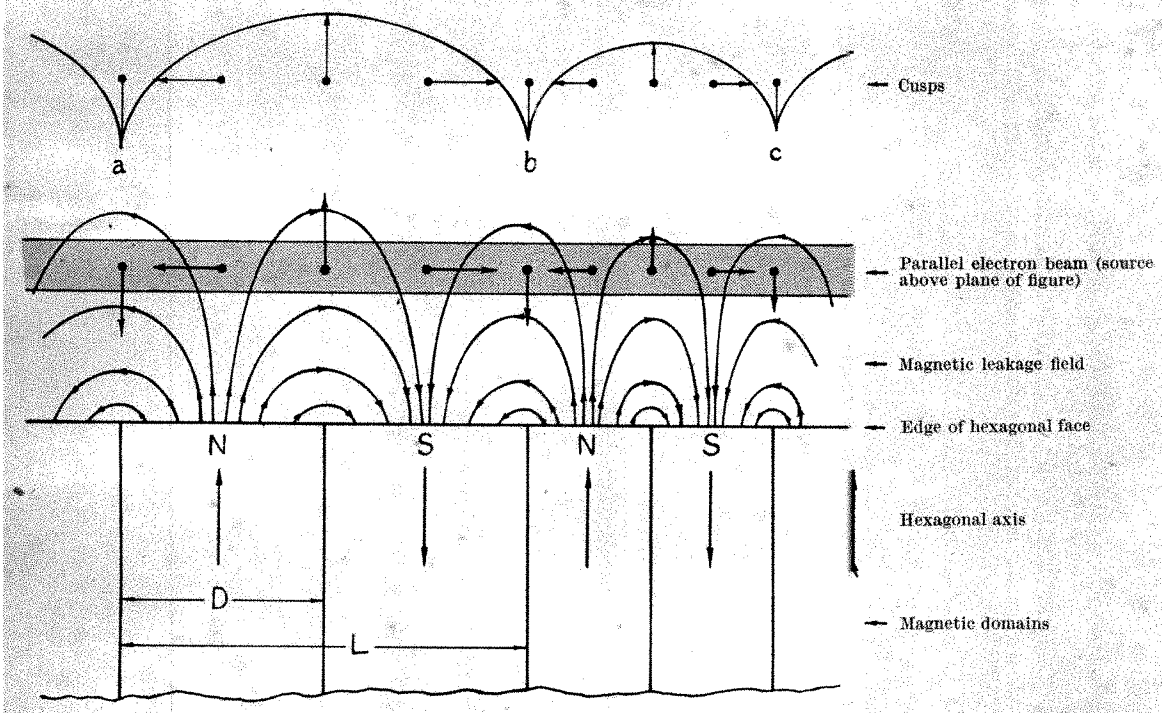

Fig. 2. Illustration of the formation of cusps

A detailed account of these and other magnetic effects will be published shortly. We are indebted to Dr. R. S. Tebble and Prof. E. C. Stoner, of the University of Leeds, for the cobalt crystals. One of us (E. G.) is indebted to the British Council for a scholarship and grant, which have enabled him to take part in this research.

Vertical Eddy Diffusion in Deep Water

The equilibrium of the uranium series in sea water is interrupted by the removal of ionium (thorium-230)[1]. The efficiency of the removal seems, according to investigations by Koczy, Picciotto, Poulaert and Wilgain[2], to be higher than 98 per cent. This means that the ionium in solution is almost completely precipitated, and the radium content of sea water must be renewed from radium produced in the sea floor by the decay of precipitated ionium. The amount of radium supplied to the ocean by river water seems to be only a few per cent of that necessary to keep the radium content of sea water at its average value of 8×10^{-17} gm. per ml. The radium is transported by currents and eddies in the deep water and is moved upwards by eddy-diffusion. The distribution of the radium in the deep water should, therefore, enable the eddy diffusion to be estimated.

As a first approximation, it is assumed that the sea floor delivers per square metre and year the same amount of radium throughout a large region of the deep sea floor, that the advection is zero, and that the distribution of radium is stationary. Then, if the decay of the radium during its transport is also taken into consideration, the following equation is obtained:

$$\frac{\partial}{\partial t}\left(\frac{A}{\rho}\,\frac{\partial c}{\partial t}\right) - \lambda c = 0$$

where c is the radium content, λ is the decay constant of radium and t is the height above the bottom or the zero-level. This equation solved in respect to A gives:

$$A(\xi) = A(0)\left(\frac{\partial c}{\partial t}\right)_{t=0} \Big/ \left(\frac{\partial c}{\partial t}\right)_{t=\xi} + \lambda\rho \int_0^{\xi} c\,(t)\,dt \Big/ \left(\frac{\partial c}{\partial t}\right)_{t=\xi}$$

In order to estimate the variation of $A(\xi)$ with depth, the eddy-diffusion at a reference-level must be known. This may be obtained if it is assumed that the eddy diffusivity in the thermocline is near zero; moreover, the eddy diffusivity must not show negative values. The derivatives are read from the smoothed curve of the distribution of radium with depth, and the integral value is also obtained by graphical evaluation.

During the Swedish Deep-Sea Expedition (1947–48), a series of radium determinations was carried out[3]. This series demonstrates that the radium content in the ocean is generally lowest at the surface and rapidly increases in deep water with decreasing stability. At two stations in the Atlantic, the distribution of radium with depth shows a more complex structure. This may be explained by the existence of the North

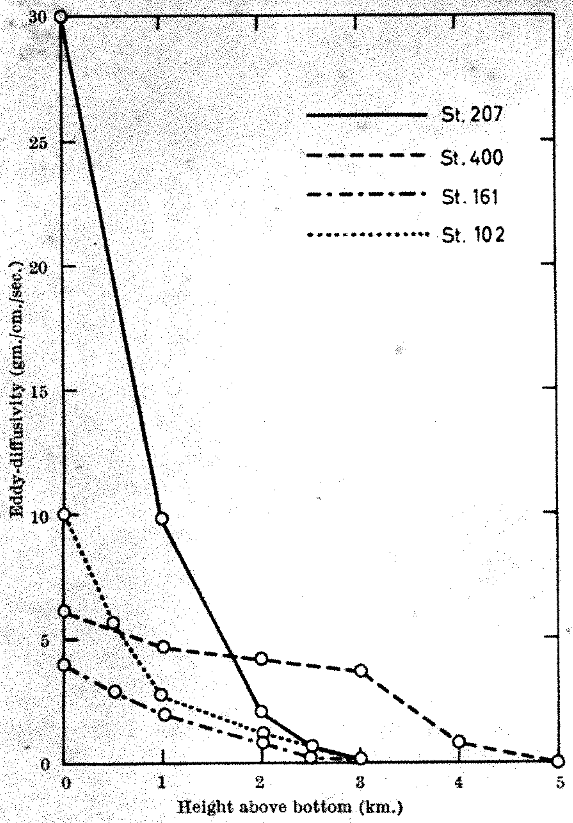

Fig. 1

Atlantic water, whereas a corresponding water mass originating in the Arctic region is absent from the other oceans. The distribution of radium in the deepest layer of the Mindanao Trench does not conform with the general pattern. For our calculations four stations were selected, one in the Atlantic, one in the Indian Ocean and two in the Pacific Ocean. Their geographical position and the total depth are as follow:

	Lat.	Long.	Depth
Station 102	13° 25′ S.	149° 30′ W.	4,630 m.
161	5° 10′ N.	127° 53′ E.	8,200
207	0° 01′ S.	88° 18′ E.	4,486
400	43° 04′ N.	19° 40′ W.	5,990

As zero-level the depth of the deepest-water sample was generally taken at a distance of about one hundred metres above the sea floor. But at Station 161 in the Mindanao Trench the mean depth of the Pacific Ocean was chosen as zero-level. The results from the calculation are given in Fig. 1.

The eddy-diffusivity near the bottom varies between 4 and 30 c.g.s. units and decreases with distance from the sea floor. The values obtained by this method are not as high as the values obtained by Wüst[4] from a dynamical calculation. One reason for this may be that the variance of the eddy-diffusivity is so high that values of 70 c.g.s. may also be obtained in certain places by our method. On the other hand, the eddy-diffusivity should always be lower than the eddy-viscosity. It must be pointed out that the lowest values of the eddy-viscosity are about a power of ten higher than our lowest value for the eddy-diffusivity.

The amount of radium given off from 1 sq.m. of the sea floor per year is given by:

$$\varphi = 3{\cdot}16 \times A(0)\left(\frac{\partial c}{\partial t}\right)_{t=0} \times 10^{11}\ \text{gm./m.}^2\text{/year}$$

The figures obtained at the four stations vary between 120 and 180 × 10^{-12} gm. radium/m.^{2}/year. The same result has been found by a different method[5] based on the total geochemical balance of the radioactive elements in the hydrosphere.

Details of this work will be given in the Reports of the Swedish Deep-Sea Expedition. I wish here to thank Östen Carlsson, of the Chalmers Technical Highschool, who has kindly carried out the calculations.

Lattice Magnetostriction in Spinel-Type Iron Chromites

Several accounts have previously been given from these Laboratories of the lattice dilatation effects that occur when monoxides and other compounds of the transition metals are cooled through their paramagnetic–antiferromagnetic transition temperatures.

Two instances of structural deformations at low temperatures in spinel-type oxides have also been reported. Thus Tombs and Rooksby[1], using X-ray powder methods, showed that in magnetite (Fe_3O_4) a rhombohedral deformation takes place below − 160° C., and Rooksby and Willis[2] found that at − 180° C. the structure of cobalt ferrite is tetragonally deformed. The rhombohedral nature of the magnetite structural change was later critically investigated by Abrahams and Calhoun[3] by magneto-X-ray single-crystal methods. Although they found some fine detail not detected in the powder work, and suggested that the true low-temperature structure is of orthorhombic or lower symmetry, the rhombohedral interpretation appears to be valid to a first approximation[4].

Besides the observations of distortions in such sodium chloride-type and spinel-type structures, measurements on ferric oxide[5] and chromium oxide[6] have disclosed lattice dilatations associated with antiferromagnetic transitions. Consequently there seemed to be grounds for predicting that lattice magnetostrictive effects similar to those already observed in in Fe_3O_4 and $CoFe_2O_4$ might occur at low temperatures in chromium-substituted cubic iron oxides, that is, in solid solutions of the general form $FeFe_{2-x}Cr_xO_4$. Confirmation of this prediction has recently been obtained by X-ray powder studies of several such iron oxide/chromite preparations, using liquid air-cooling and gas-cooling techniques.

When observations are made at − 180° C., for compositions in which the value of x in the solid solution lies between 0·2 and 0·8 the structural deformation established as characteristic of Fe_3O_4 becomes vanishingly small. At $x = 1{\cdot}0$, however, a new tetragonal-type distortion becomes evident at liquid-air temperature, and for $x = 1{\cdot}2$ the

	a_0 (A.)	a_0 (A.)	c_0 (A.)	c/a
1·0	8·396	8·384	8·392	1·001
1·2	8·405	8·369	8·410	1·005
2·0	8·377 (± 0·001)	8·454	8·187	0·968

magnitude of this distortion has increased appreciably, as shown in Table 1.

The results obtained for the solid solutions led us to believe that with pure ferrous chromite, $FeCr_2O_4$, an even larger lattice dilatation effect might be obtained at liquid-air temperature. Examination disclosed that, although the tetragonal deformation was indeed larger in magnitude, there was a change in its sense. The tetragonality observed was the result of a relative contraction, instead of expansion, in one of the [001] directions, so that the axial ratio was less, not greater, than 1·0 (see Table 1).

It will clearly be of considerable interest to examine the low-temperature behaviour of compositions between $x = 1{\cdot}2$ and $x = 2{\cdot}0$. X-ray studies are now being carried out on several solid solutions lying in this range, and it is hoped to present all the results in detail elsewhere.

The mechanism by which the structure cell of spinel-type oxides of this type deforms from its room-temperature cubic symmetry on cooling through a certain critical temperature is not yet properly understood. It would appear likely, however, that the lattice dilatation effects are linked with alterations of the magnetic dipole alignments such as have been discussed by Li[7] in connexion with simple anti-ferromagnetic monoxides and other compounds. It is possible that an extension of Li's arguments on spontaneous magnetostriction to the spinel-type compounds will explain all the various structure changes that have been described above.

Ductility in Chromium

Much recent work has been carried out on the preparation and properties of pure chromium with the aim of establishing chromium base alloys as engineering materials. The obstacle to this, the room-temperature brittleness, has naturally attracted great attention. It has been suggested that the brittleness of chromium is promoted by nitrogen content above 20 p.p.m., by rough surface condition and by recrystallization. It had been found previously that the greatest lowering of the ductile/brittle transition temperature in chromium is obtained in polished pieces which have been worked below the recrystallization temperature. Complete recrystallization in rolled chromium raises the transition temperature so that there is usually no bend ductility at room temperature, although pieces in this condition showing ductility have been produced[1].

Recently, we have found that the main source of nitrogen in electrolytic chromium is the presence of nitrates in the electrolyte of a conventional hexavalent chromium bath and that nitrogen in other forms such as ammonia or air has no appreciable effect on the composition of the deposited metal.

We have also found that chromium produced by the lubricated extrusion of sheathed, compacted flakes can show ductile behaviour in bend tests, even though the nitrogen content is as high as 900 p.p.m. An electro-polished piece made in this way, and having an insoluble content of 1·25 per cent and a nitrogen content of 0·091 per cent, showed ductile bend behaviour at a temperature of − 30° C., but broke in a brittle manner at − 50° C. Charpy-type impact tests on a low-nitrogen piece of this extruded chromium gave results of 2·17 ft.lb. at room temperature and 5·74 ft.lb. at 250° C. using machined, unnotched specimens of 1 cm. square cross-section. These figures can be compared with corresponding values of 0·4 and 0·6 ft.lb. respectively for tests on similar-sized chromium bars made by sintering chromium powder in purified hydrogen. X-ray diffraction examination of the extruded chromium showed it to be in a fully recrystallized condition.

It therefore appears that the extrusion method indicated above has an effect of increasing ductility and lowering of the transition temperature which over-rides the opposing effect of nitrogen content and recrystallization. Clearly a measure of preferred orientation may be produced by the extrusion and this may be playing an important part in the effect. This is being investigated.

Application of the Schlieren Technique to the Study of Ripples

In the simplest form of ripple tank demonstration, a 'point' source of light placed below the tank is used for casting 'shadows' of the ripples on a screen. The ripples have a complicated lens action on the light, so that the relation between the pattern of ripples on the water surface and the pattern of light and shade on the screen is not necessarily a simple one: caution must be exercised in interpreting the finer details of the pattern observed. In more complicated forms of the apparatus, a lens is used above the tank for projecting on to the screen a real image of the ripples; but the same difficulty arises. If the water surface is in sharp focus, the ripples are almost invisible. The lens must be raised so that it focuses the focal lines of light produced by the ripple crests. Now the distance of these focal lines above the surface of

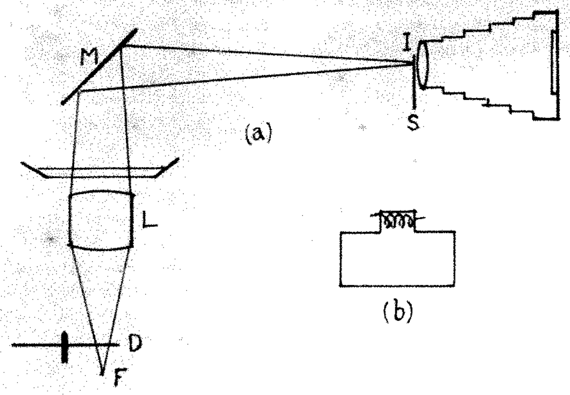

Fig. 1

the water depends on the curvature of the ripples, and since this varies with the attenuation of the waves, it is impossible for the pattern to be in sharp focus over the screen, while obstacles introduced into the tank to produce reflexion, refraction or diffraction are always out of focus.

The schlieren technique, normally used for revealing regions of varying refractive index in a gas, appears to offer a solution of the problem. In the arrangement (Fig. 1) used for obtaining the accompanying photographs, an epidiascope lens *L* of 4 in. aperture was mounted, with axis vertical, immediately below the tank. The source was a micro-projector lamp, *F* (30-W., filament size 3 mm. × 2 mm.), placed so that the lens focused its light through the tank to form a real image 9 mm. × 6 mm. For convenience, the axis of the beam is made horizontal by the surface-silvered mirror *M*. The image of the filament is thus focused at *I* in front of the camera lens and the camera itself is focused on the surface of the water. The image *I* is intercepted by the screen *S*. (The shape of *S*, with image *I* superimposed, is shown at Fig. 1*b*.) The field of view on the camera screen thus becomes uniformly dark. Any disturbance on the surface of the water which deflects light upwards or sideways will appear bright on the screen and the ripples are thus made visible. The lens of the camera should be used at full aperture, with the shutter open, and an exposure made by uncovering *F*.

The photographs (Fig. 2) show: (*a*) partial reflexion, refraction and interference of linear waves originating in deep water and impinging on the apex of a triangular patch of shallow water; (*b*) passage of waves from shallow into deeper water, with total internal reflexion and interference; (*c*) interference of light from two point sources.

The ripples were produced by a vibrator driven from 50 ~ supply, and a stroboscopic disk was used at *D*. The exposure was about ¼ sec. Work is now in progress on ciné-photography of the ripples.

X-Ray Hazard in Sputtering Apparatus

In a paper to be published in the *Proceedings of the Physical Society* on the "Bombardment of Various Elements by Hg$^+$ and A$^+$ Ions", we have described sputtering experiments with low-pressure gas discharge tubes where an appreciable intensity of X-radiation was observed. It has been pointed out to us that, whereas the hazards of X-rays in magnetrons[1], gas-filled[2] and vacuum valves are well known, the indirect production of X-rays during sputtering at high voltages would be generally unsuspected, and that the matter should be given wider mention.

The discharge tubes used in these experiments had each an oxide-coated flat nickel-strip cathode and an 'Armco' iron anode. The discharges were formed in argon or mercury vapour at currents ranging from 0·1 to 15 amp., with a cathode-to-anode voltage drop of about 20 V. The targets were attached to side arms sealed to the discharge tubes and were exposed to the discharge plasma. Negative potentials of up to 20 kV. were applied to the targets so that they were bombarded by positive ions drawn from the discharge. The target currents depended on the experimental conditions and ranged from 0·1 to 10 m.amp. With the various targets studied, including carbon, iron and uranium, copious secondary electron emission by positive ion bombardment was found at the higher voltages. The X-rays observed were shown to arise from the acceleration of these electrons across the positive ion sheath surrounding the target and their subsequent collision with the walls of the discharge tube. At 8 kV. and above, the X-rays were detected by the fogging, within an hour or so, of Ilford dental X-ray film placed about six inches from the tube, indicating radiation intensities at that point of roughly 10^{-5} r./sec., which exceeds the maximum permissible dose-rate.

Thus in similar experiments or industrial processes involving ion bombardment at, say, 10 kV. and

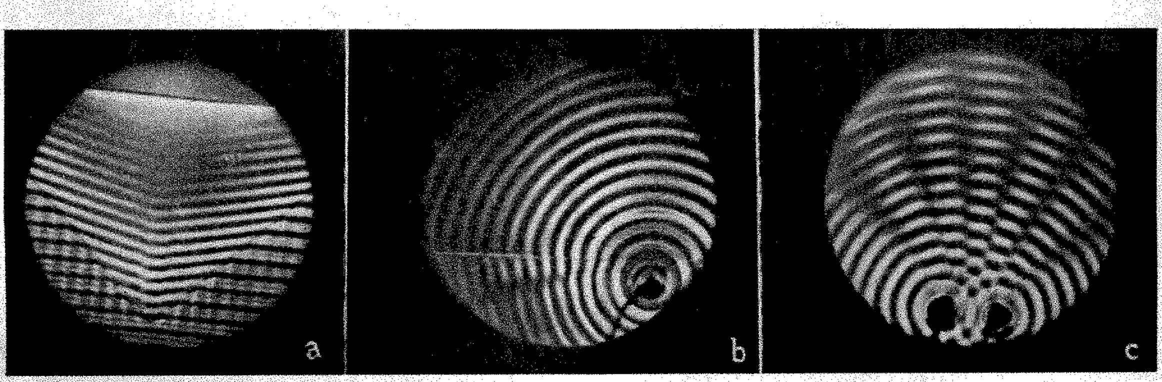

Fig. 2

above, it is essential to test for X-rays, and to shield against them if they present a hazard to personnel.

Existence of a Non-Electrostatic Stabilizing Factor in Hydrophobic Selenium Hydrosols

It is well known that the stability factor of hydrophobic sols decreases, at first, exponentially with the ionic strength of the solution, and reaches, rather suddenly, its limiting value for a certain concentration C_1 of the coagulating electrolyte[1]. For concentrations lower than C_1 we have the so-called 'slow coagulation'; the interaction energy consists of long-range electrical repulsions, dependent on ionic strength, and of Van der Waals attractions. For concentrations higher than C_1, the electrical repulsions have practically disappeared[2] and we have 'rapid coagulation'.

The kinetics of rapid coagulation have been studied theoretically. Each particle is assumed to be surrounded by a sphere of attraction having a radius r. If the centre of a second particle penetrates into this sphere of attraction, the two coalesce irreversibly. Treating the problem as one of simple diffusion, von Smoluchowski[3] showed that the disappearance of primary particles must initially be a bimolecular process, characterized by a kinetic constant:

$$k_{1\cdot 1} = \frac{4kT}{3\eta} \cdot \frac{r}{a}$$

where k is Boltzmann constant, T is the absolute temperature, η is the viscosity of the medium and a is the radius of the particles.

The ratio r/a must obviously have a value of at least 2, and Hamaker[4] has shown that it should be slightly larger. Experimental values between 2 and 3 have been found in a number of cases.

However, for selenium hydrosols, Kruyt and Van Arkel[5] found very small values ranging from 0·55 to 1·3. With sols prepared in a similar manner, we have confirmed their results, obtaining values between 0·58 and 1·06, as shown in Table 1. It therefore appears that for selenium sols, some repulsive force unconnected with the charge of the double layer must be taken into account.

We have found that the abnormal stability is due to an impurity, probably hydrazine hydrate, which is used as a reducing agent for preparing the sols.

Table 1. Experimental Values for the Ratio r/a, with Non-dialysed Selenium Hydrosols

Sol concentration (No. of particles/cm.^{3})	Diameter of particles (mμ)	r/a
$0\cdot62 \times 10^9$	188	1·06
0·96	168	0·84
3·14	142	0·58
1·57	142	0·62
0·78	142	0·77

Table 2. Variation of the Ratio r/a during Purification of a Selenium Hydrosol

Time of electrodialysis (hr.)	Conductivity of the sol (ohm^{-1} cm.$^{-1}$)	r/a
0	$133\cdot0 \times 10^{-6}$	1·5
22·5	118·0	1·8
29·75	95·5	2·1
46·0	57·0	2·3
71·0	8·8	2·2
78·5	8·0	(3·9)
118·5	6·5	2·1
167·0	4·2	2·2

The numerical data given in Table 2 show clearly that when the colloidal solutions are purified by prolonged electrodialysis, the ratio r/a increases regularly with the purity, as measured by specific conductivity.

In another series, r/a varied from 0·44 to 2·5 during purification.

It must be stressed that the purification has practically no influence on the stability factor in the region of slow coagulation, or on the limiting concentration C_1. Therefore, it does not affect the Stern potential.

A tentative explanation of this behaviour is that each micelle is covered by an adsorbed layer of hydrazine, and this strongly polar substance modifies the local structure of water in the immediate neighbourhood of the colloidal particle. The 'hydration' shell may cause a repulsive action of entropic origin—a steric hindrance.

Synthesis of 4-Methylumbelliferone β-D-Glucuronide, a Substrate for the Fluorimetric Assay of β-Glucuronidase

At the present time there is considerable demand for a suitable synthetic substrate for the routine assay of β-glucuronidase. The most common assay method employs phenolphthalein glucuronide isolated from rabbit urine[1]. However, the preparation of 4-methylumbelliferone glucuronide from rabbit urine and its use in the fluorimetric assay of β-glucuronidase have been recently described[2]. This substrate promises certain advantages over phenolphthalein glucuronide, and it is easy to synthesize, by the method previously employed for (−)-menthol[3] and phenol[4] β-D-glucuronides.

4-Methylumbelliferone β-D-glucoside hemihydrate[5] (1·5 gm.) in 60 ml. water was maintained at 90° C. and vigorously stirred. Oxygen was passed into the solution through a sintered glass disk, and freshly reduced platinum catalyst[3] (0·4 gm.) was added. The pH was kept between 7 and 9 throughout the oxidation by the addition of 0·5 N sodium bicarbonate. After 1 hr., more catalyst (0·2 gm.) was added, and the reaction was complete 30 min. later, with an almost theoretical uptake of alkali. The filtered solution was reduced to half volume, treated with charcoal, and made acid to congo red with hydrochloric acid. The hydrated glucuronide was filtered off and recrystallized from 50 per cent (v/v) aqueous ethanol and then from water : yield 0·95 gm. (54 per cent). After drying at 105° over phosphorus pentoxide, the hemihydrate[2] had corrected and mixed melting points with a biosynthetic specimen of 139–140°, and $[\alpha]_D^{22}$ $-119°$ in water (*c*, 0·25) : on acid hydrolysis 4-methylumbelliferone was obtained, melting point and mixed melting point 187–188°. Mead *et al.*[2] give a melting point of 139–140° (decomp.) for the hemihydrate of the biosynthetic glucuronide, and $[\alpha]_D^{23}$ $-105°$ for the completely hydrated compound.

Grateful acknowledgment is made to Prof. R. T. Williams and Dr. D. Robinson for specimens and unpublished results.

Phase-Change in 1,2,4,5-Tetrabromobenzene investigated by Pure Quadrupole Resonance

It is the purpose of this communication to mention a result of a type which we believe to be hitherto unreported, which we obtained when the temperature dependence of the bromine-81 pure quadrupole resonance at about 240 Mc./s. in 1,2,4,5-tetrabromobenzene was investigated. Here, on raising the temperature above 20° C., there is as usual a linear decrease of frequency. However, a very sudden discrete drop occurs at 46·5° C., after which there is again a linear decrease. On then reducing the temperature, the increase of frequency is linear as far as 33·5° C., where there is a sudden discrete rise, the frequency returning to the original line and completing a hysteresis loop.

The experimental results are shown in Fig. 1. The temperature coefficients of frequency are $-3·9 \times 10^{-5}$/deg. C. and $-5·9 \times 10^{-5}$/deg. C. for the upper and lower straight line portions respectively. The frequency jump is of the order of 1·5 parts in 10^3. It is interesting to note that the temperature coefficient at temperatures above the discontinuity is of the order usually found in compounds where bromine is attached to the benzene ring, while that at temperatures immediately below is about 35 per cent lower.

The resonance was obtained by means of an externally quenched frequency-modulated super-regenerative oscillator using a cathode-ray oscillograph display. A push–pull arrangement was used employing type 955 'acorn' triodes, the sample being placed in a tuned coil at the far end of the anode lines. A simple oven surrounds the specimen. Comparison between frequency measurements made with slowly rising and slowly falling temperatures indicates that the error of temperature measurement is ± 0·2° C.

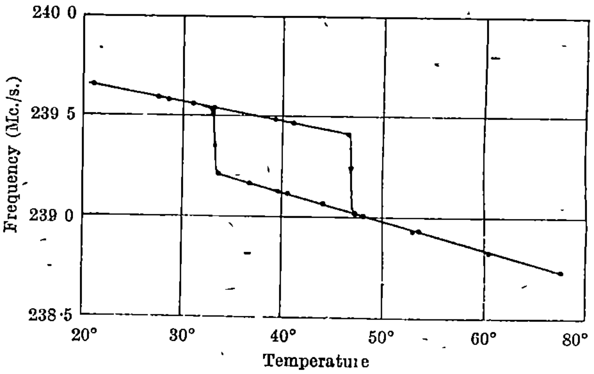

Fig. 1. Frequency of bromine-81 pure quadrupole resonance in 1,2,4,5-tetrabromobenzene as a function of temperature

Frequency measurements were made by adjusting the amplitude and frequency of quench so that the resonance appeared as a single peak. This was then located at the centre of the cathode-ray oscillograph display. The sweep- and quench were then switched off, and the frequency of the oscillator measured by obtaining zero beat with a harmonic of a calibrated wave-meter, type *BC*-221-*C*, detected by means of a G.E.C. very high frequency panoramic receiver, type *BRT*-652. The calibration of the wave-meter was set for each reading by means of the 2 Mc./s. crystal incorporated in the receiver. This was, in turn, checked against a B.B.C. transmission at 94·3 Mc./s., which afforded a sufficiently accurate standard at a convenient frequency. This system of measurement gives an error of about ± 5 parts in 10^5, which includes that of setting the oscillator exactly upon the quadrupole frequency.

Thanks are due to Mr. D. Pardy for carrying out the measurements.

Factors affecting the Permanency of Paper : Tests with Labelled Sulphur

Papers of good quality and high alpha-cellulose content can be kept under suitable storage conditions for several centuries. There are, however, differences of opinion on factors affecting storage, and a recent investigation by Langwell[1–5] claims that even good-quality papers can become brittle at the edges. He stated that this attacked portion of the paper in old documents and books has a scorched appearance resembling the product of the reaction between cellulose and strong acid. Analyses of these old papers reveals a high sulphate content indicative of attack by sulphuric acid from the atmosphere.

The concentration of sulphur dioxide in industrial atmospheres is of the order of 0·5 part per million[6], and Langwell has suggested that catalysts in the paper accelerate the conversion of this sulphur dioxide to sulphuric acid. By exposing paper, usually under damp conditions, to atmospheres containing about 0·5 per cent sulphur dioxide, that is, 10,000 times that in an industrial atmosphere, Langwell measured the increase in sulphate in the paper by extraction with water and precipitation as barium sulphate. The uptake of sulphur was correlated with catalysts present in, or added to, the paper, and ron was found to be an important catalyst for the conversion of sulphur dioxide to sulphate under these conditions.

His work was limited by the sensitivity of the precipitation method. One of us had found, in another connexion[7], that sulphur-35 could be used very effectively in paper for studying migration by autoradiographs or counting. We therefore decided to repeat some of Langwell's experiments using sulphur labelled with sulphur-35. W. H. Langwell, imself, kindly supplied us with the same papers that he had used in studying the effect of catalyst nhibitors[4].

Detailed results will be published elsewhere, when hey are complete, but some new information has een found already. Using a wet atmosphere and 0·5 per cent sulphur dioxide the uptake of sulphur dioxide could be detected with a Geiger–Müller ounter after 2-hr. exposure only, and after 24-hr. exposure the papers tested could be shown to fall in general into the order already found by Langwell using a seven-day exposure.

Some labelled sulphur was burned in a desiccator o give a concentration of 1 per cent sulphur dioxide under normal dry conditions (about 50 per cent elative humidity). When papers were exposed to his the uptake of sulphur dioxide could be detected n 3 hr., and after 24 hr. the papers again fell into the order obtained by Langwell.

It was necessary to expose all papers to atmosphere efore counting to allow gaseous sulphur dioxide to diffuse out; but a steady counting-rate was obtained after 4 hr.

The labelled paper samples after exposure to ulphur dioxide under both wet and dry conditions were placed between X-ray film for three weeks and hen developed. The autoradiographs showed some general take-up of sulphur; but they also showed a andom distribution of intense black spots with dark areas spreading from them. The paper itself was now developed with acid potassium ferrocyanide and it was found that the dark areas corresponded to iron, and in some cases, bronze spots in the paper. The take-up of sulphur dioxide is, therefore, partly general and partly localized.

Detonation Phenomena in Homogeneous Explosives

In their discussion of certain detonation phenomena in homogeneous explosives, Campbell *et al.*[1] describe a curious effect obtained by lining the container of an explosive with metal foil. They state that very thin metal foils, of the order of 0·001 in. thickness, can reduce quite considerably the diameter at which failure of detonation of nitromethane occurs.

In considering the effect of the container on the detonation of an explosive charge, the natural impulse is to look for an interpretation of the phenomenon in terms of confinement, by which is usually meant the resistance offered by the envelope to the lateral expansion of the detonation products. It is known, however, that the initial mass movement of the products, or 'streaming velocity', is forward, from which it may be deduced that the early stages of detonation are more likely to be influenced by resistance to forward, rather than to lateral, movement. This suggests that frictional resistance at the surface may be a more potent factor initially.

That this effect exists is indicated by the fact that detonation in a gaseous explosive is established sooner in a tube with a rough interior than in one which is smooth. Also, detonation sets in earlier in a narrow tube than in a wide one[2]. These facts show that the onset of detonation is governed by conditions at the surface and that the roughness of the surface is involved. The inference is that frictional resistance at the surface, which is a tangential force and so does not oppose lateral movement, is a significant factor in the development of detonation.

In detonation, very high pressures and velocities are involved and, as violent friction causes abrasion and erosion, the surface material is reduced and is able to mix, and possibly react chemically, with the products of detonation, much as coal dust is raised and consumed in a mine explosion. The violent explosions which have occurred in oil-contaminated compressed-air lines[3], the independent propagation of detonation in tubular cavities in high-explosive cartridges[4], and the low-velocity detonation regime in cartridges of granular explosive[5], are probably further instances of surface films taking part in high-velocity explosive reactions. Thus the action of the surface layer can be chemical as well as physical.

Activation of Phospholipid Thromboplastin by Lecithin

This communication is prompted by the recent report of Newlands and Wild[1] that a preparation of soybean phospholipid can serve as a useful source of platelet factor for the thromboplastin generation test. We have been trying in this laboratory for several years to define the phospholipid structures responsible for thromboplastic activity. Reports have been limited to preliminary communications[2-4] because the degree of purity of the active fractions does not permit a rigorous correlation of structure with activity, although the evidence suggests that the essential structural requirement is the presence of a serine or ethanolamine base in a glycerophospholipid molecule. It should be noted that the activity discussed in this communication is acceleration of the conversion of prothrombin to thrombin in the presence of calcium and a suitable (glass) surface in mammalian coagulation systems. Phosphatidyl serine, which has a higher activity per unit weight than thromboplastic protein in accelerating prothrombin conversion in the rabbit system[2], is without effect when studied with avian plasmas.

The discovery of the activating effect of lecithin arose from two observations. The first was that individual fractions of cephalin, precipitated from methanol according to Maltaner[5], did not show greater activity as their content of amino-nitrogen containing phospholipid increased. The second was that the step in which crude cephalin is precipitated from an ether extract of brain by the addition of ethanol according to the method of Folch[6] led to a loss of 90 per cent of total activity. The activity could be recovered if the fractions were recombined in an organic solvent before the lipid was suspended in aqueous medium for testing. The major component of the less active, ethanol-soluble fraction was lecithin. While the addition of an aqueous suspension of lecithin had no effect, or was at most slightly inhibitory, when added to an aqueous suspension of phospholipid thromboplastin[3], the prior combination of the two in organic solvents had not been tried.

In the present experiments thromboplastic activity was determined as previously described[2]. The source of lipid thromboplastin was a cephalin fraction of beef brain prepared by Maltaner twenty years ago[5] and stored under ethanol. It was as active as fresh preparations, attesting to the exceptional stability of the active component. Analysis of this material showed phosphorus, 3·7 per cent; nitrogen, 1·59 per cent; and serine, 11·4 per cent. Three lecithins were studied: a highly purified egg lecithin, dipalmitoleyl lecithin from yeast and beef heart lecithin (the major component of which was recently shown to be phosphatidal choline, a choline-containing plasmalogen). The lecithins had no thromboplastic activity. The phosphatidyl serine fraction in toluene was combined with a solution of lecithin in toluene. The organic solvent was completely removed under reduced pressure and the lipid suspended in saline. The curves in Fig. 1 show the dependence of clotting time on the logarithm of quantity of cephalin for this preparation of beef brain phosphatidyl serine by itself and in the presence of a two-fold quantity of lecithin. It is apparent that the lecithin–cephalin mixture is ten times as active as the cephalin alone, when comparison is made in the optimal region of the curve (that is, where clotting time reflects most sensitively changes in quantity of active substance and is still sufficiently short to permit sharp endpoints of 50–100 sec.). This represents an increase greater than three-fold based on total weight of combined phospholipids. A smaller activation was obtained when the phosphatidyl serine preparation was combined with either an equal quantity of lecithin or five times the quantity of lecithin, indicating that the activation phenomenon is characterized by optimal proportions and cannot therefore be considered to result entirely from enhanced solubility of lipid through mixed micelle formation. A ten-fold quantity of lecithin was inhibitory. It has not been possible to substitute synthetic saturated phosphatidyl ethanolamine or phosphatidyl choline for the natural products, which may be attributed to the difficulty of preparing suitable aqueous suspensions. The phenomenon described here recalls the activation of lipid antigens by lecithin and cholesterol[7], and suggests that the biological properties of phospholipids must be considered in relation to lipid–lipid interactions rather than as discrete functions. Thus identification of 'active lipid' either associated with protein (for example, thromboplastic lipoprotein, lipoprotein antigens) or free, becomes a much more complex problem. With respect to the substitution of lipid thromboplastin for platelet factor in the thromboplastin generation test, the finding that lecithin activates the thromboplastic properties of cephalin should permit a product to be formulated with any desired degree of activity, rather than leaving to chance the isolation of suitable material.

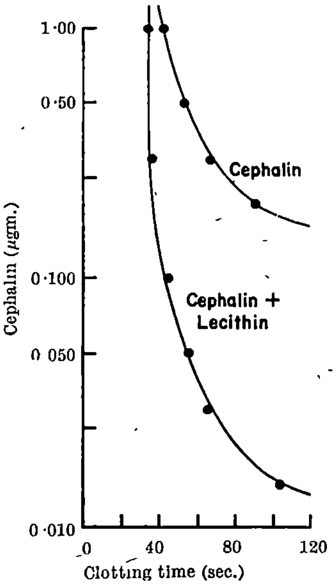

Fig. 1

I wish to thank Dr. Liselotte Graf, Mr. Nicholas Alonzo and Mr. Bernard Lerner for their co-operation and analytical assistance. I am also indebted to Dr. Donald J. Hanahan for the specimen of dipalmitoleyl lecithin and to Dr. Erich Baer for the synthetic phospholipids.

Isolation of (−) S-Methyl-L-Cysteine from Beans (*Phaseolus vulgaris*)

THE recent isolation[1,2] of S-methyl-L-cysteine sulphoxide from two crucifers, turnips and cabbage, and the chromatographic evidence[3] for its occurrence in many related plants suggested the possibility that methyl cysteine should also occur in plants. In addition, preliminary evidence has clearly indicated that the turnip can readily form the sulphoxide from methyl cysteine. A careful examination[3] of the protein and non-protein fractions of several crucifers revealed no methyl cysteine. Previous work[4] on the non-protein amino-acids of bean seeds showed a ninhydrin-reactive spot which gave an iodoplatinate test[5] indicative of the sulphur amino-acids. This material was found on a two-directional chromatogram (phenol : butanol–acetic acid) in a position corresponding to that of methyl cysteine and close to that of γ-amino-butyric acid. This compound has been isolated and identified as (−) S-methyl-L-cysteine.

Dry kidney bean seeds were ground and extracted with 50 per cent alcohol. The extract was treated with mercuric acetate, and the resultant precipitate was separated and decomposed with hydrogen sulphide. After removal of mercuric sulphide, the solution was passed through a column of sulphonic acid ion exchange resin ('Dowex 50-*X*4') in the acid form and the column was washed. The amino-acids which were retained by the resin were fractionated by displacement chromatography with 0·10 *N* ammonia[6]. The fractions containing the unknown material were contaminated with glutamic acid and asparagine. These three compounds were separated by chromatography on a paper roll[7] using 70 per cent ethanol. The unknown material was purified by three crystallizations from 95 per cent ethanol. Approximately 150 mgm. were obtained from 5 kgm. of beans. The isolate was found to be identical with synthetic (−) S-methyl-L-cysteine with respect to infra-red spectra, optical rotation $[\alpha]_D^{25^\circ} = -26^\circ$ ($c = 2{\cdot}5$), decomposition point (about 220° C.), and paper chromatography in phenol, butanol–acetic acid and collidine–lutidine ($R_F = 0{\cdot}71$, $0{\cdot}27$ and $0{\cdot}38$, respectively). The elementary analysis of the isolate was C, 35·6 ; H, 7·0 ; N, 10·2 ; S, 23·5. The calculated values are C, 35·6 ; H, 6·67 ; N, 10·37 ; S, 23·7.

The presence of methyl cysteine in legumes and its sulphoxide in crucifers suggests that these two related compounds may have a widespread occurrence in plants. This possibility, coupled with the preliminary evidence of their interconversion, may foreshadow an interesting metabolic role for the methyl cysteine–methyl cysteine sulphoxide system in plants.

Malate Synthesis in a Cell-free Extract from a Crassulacean Plant

EXTRACTS of spinach leaves[1] and of wheat germ[2] contain a phosphoenolpyruvic carboxylase which, in the presence of magnesium or manganese ions, catalyses the reaction:

$$\text{phosphoenolpyruvate} + \text{CO}_2 \rightarrow \text{oxalacetate} + \text{orthophosphate} \quad (1)$$

In the presence of reduced diphosphopyridine nucleotide and malic dehydrogenase, the oxalacetate is reduced to malate :

$$\text{oxalacetate} + \text{DPNH} \rightarrow \text{malate} + \text{DPN} \quad (2)$$

The linked reaction,

$$\text{phosphoenolpyruvate} + \text{CO}_2 + \text{DPNH} \rightarrow \text{malate} + \text{DPN} + \text{orthophosphate} \quad (3)$$

may then be followed spectrophotometrically by measuring the decrease in absorption at 340μ caused by the oxidation of reduced diphosphopyridine nucleotide.

It has been suggested that phosphoenolpyruvate carboxylase may function in the synthetic accumulation of dicarboxylic acids in plant tissues and especially in those of the Crassulaceae[2,3]. This communication reports that the leaves of *Kalanchoë crenata* and two other Crassulacean plants contain this enzyme. Extracts of *Kalanchoë* leaves known to contain malic dehydrogenase brought about a rapid oxidation of reduced diphosphopyridine nucleotide in the presence of phosphoenolpyruvate and magnesium or manganese ions. Phosphoenolpyruvate could not be replaced by pyruvate and adenosine triphosphate. There was no appreciable decrease in absorption when reduced triphosphopyridine nucleotide was substituted for reduced diphosphopyridine nucleotide.

Pre-incubation of phosphoenolpyruvate with the leaf extract and magnesium ions caused increases in the initial rate of oxidation of added reduced diphosphopyridine nucleotide. A two-stage reaction is implied by the fact that, within limits, the initial rate of oxidation was directly related to the length of the pre-incubation period.

Production of malate during the course of the linked reaction (3) has been shown chromatographically and the hydrazone of oxalacetic acid prepared, and separated, from reaction mixtures containing no reduced diphosphopyridine nucleotide. Labelled malate and labelled oxalacetic hydrazone have been similarly prepared by adding radioactive bicarbonate to the appropriate reaction mixture. This is believed to be the first demonstration of malate synthesis *in vitro* catalysed by a cell-free preparation from a Crassulacean plant.

Bandurski[3] has reported a stimulation of phosphoenolpyruvic carboxylase by carbon dioxide. This has been confirmed by Brown[4] and by myself, who found a linear relationship between the reciprocals of reaction-rate and the reciprocals of (low) concentrations of both phosphoenolpyruvate and carbon dioxide. Between 0·1 and 10 per cent the rate of the linked reaction was affected only slightly, rising gradually below 0·5 per cent and then declining. Above 10 per cent this decline became pronounced, and the reaction was almost completely inhibited in 70 per cent carbon dioxide (that is, in a solution containing the bicarbonate calculated from the Henderson Hasselbach equation[5] to be in equilibrium with an atmosphere containing 70 per cent carbon dioxide). As malic dehydrogenase was not depressed by carbon dioxide, it is presumed that reaction (1) was inhibited. There is a strong parallelism between this behaviour and the effect of carbon dioxide on dark acidification in the intact leaf[6]. This is consistent with the view that phosphoenolpyruvic carboxylase is the enzyme which actuates such acidification *in vivo*.

Net Synthesis of Lecithin in an Isolated Enzyme System

WORK in this Laboratory[1] has shown that the biosynthesis of lecithin and of phosphatidyl ethanolamine involves the intermediary formation of cytidine diphosphate choline and cytidine diphosphate ethanolamine. The enzymatic synthesis of lecithin is described in the following simplified scheme:

$$\text{Cyt-P-O-P-O-P} + \text{P-choline} \longleftrightarrow \text{Cyt-P-O-P-choline} + \text{P-O-P} \quad (1)$$

$$\text{Cyt-P-O-P-choline} + \text{D-}\alpha,\beta\text{-diglyceride} \longleftrightarrow \text{Lecithin} + \text{Cyt-P} \quad (2)$$

Previous experiments on the biosynthesis of lecithin in isolated enzyme systems have required the use of isotopic tracers, since the amounts of newly formed phospholipid were too small to be detected by conventional chemical methods. In such experiments, it was impossible to rule out the occurrence of reactions by which the labelled compound exchanges with the phospholipid in the enzyme preparation, bringing about an incorporation of the isotope without a net increase in phospholipid.

It has now been found that isolated mitochondria, incubated with cytidine diphosphate choline and D-α,β-diglyceride, catalyse the net synthesis of lecithin (Table 1). During the course of incubation with the complete system, the amount of phospholipid is almost doubled. Synthesis falls to a low level if the diglyceride is omitted, and no synthesis occurs if the cytidine diphosphate choline is omitted. It is necessary to carry out the reaction in the presence of small amounts of a surface-active agent such as 'Tween-20' (polyoxyethylene sorbitan monolaurate) in order that the diglyceride may penetrate to the site of enzymatic synthesis. There is good agreement when the synthesis as measured by the incorporation of radioactive choline from the cytidine diphosphate choline is compared with the net increase in lipid phosphorus.

Table 1. THE NET SYNTHESIS OF LECITHIN IN AN ISOLATED ENZYME SYSTEM

Additions	Lipid phosphorus (microatoms)	Δ Lipid phosphorus (microatoms)	Total counts incorporated
1. None	1·19	—	—
2. Cytidine diphosphate choline	1·23	0·04	960
3. D-α,β-diglyceride	1·17	0	—
4. Cytidine diphosphate choline + D-α,β-diglyceride	2 25	1·06	13,375

Each tube contained 20 μmoles magnesium chloride, 10 μmole cysteine, 40 μmoles tris(hydroxymethyl)aminomethane buffer o pH 7·4, 2 mgm. of 'Tween-20' and 8 mgm. of mitochondria from chicke liver in a final volume of 1 ml. Cytidine diphosphate choline (3 μmoles labelled with choline-1,2-^{14}C (14,000 counts/μmole/min.) was adde where indicated. D-α,β-diglyceride (4 μmoles), prepared from eg lecithin by the action of lecithinase from *Clostridium perfringens*, wa also added to some tubes as shown. The tubes were incubated at 37 for 2 hr. The lipid fraction was isolated, counted and analysed fo total phosphorus as described in ref. 4.

Work in several laboratories[2] has led to the discovery in liver and brain of enzyme systems which rapidly synthesize phosphatidic acids. However, phosphatidic acids do not occur in appreciable concentrations in these tissues. Considerable speculation has therefore arisen as to the role of phosphatidic acids in the metabolism of lipids. It has now been found that mitochondria and microsomes from rat liver catalyse the reaction:

$$\text{Phosphatidic acid} \rightarrow \text{D-}\alpha,\beta\text{-diglyceride} + \text{inorganic phosphorus} \quad (3)$$

The dephosphorylation is inhibited by magnesium ions and 'Tween-20'. Therefore, if phosphatidic acid is added to enzyme systems such as shown in Table 1, which are synthesizing lecithin in the presence of magnesium ions and 'Tween-20', no stimulation of synthesis occurs. If the phosphatidic acid is preincubated with the enzyme, and then 'Tween-20', magnesium ion and labelled cytidine diphosphate choline are added, a stimulation of synthesis is observed (Fig. 1) which is proportional to the time

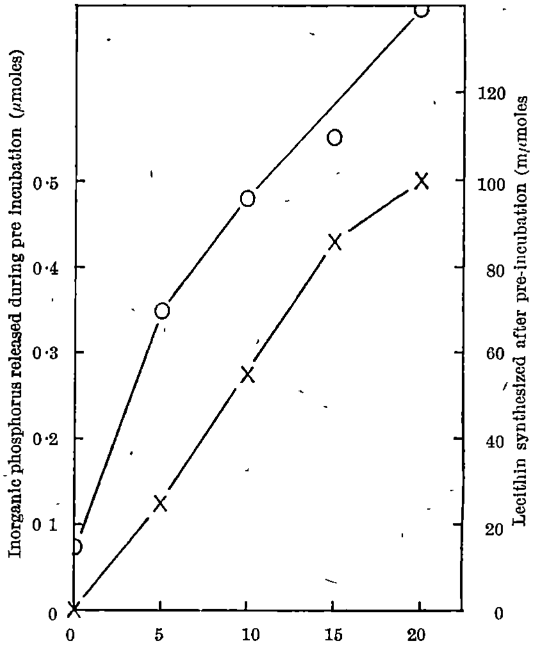

Fig. 1. 4·0 μmoles of phosphatidic acid were pre-incubated at 37° with 50 μmoles of tris(hydroxymethyl)aminomethane buffer of pH 7·4 and 2 mgm. of microsomes from rat liver for the time intervals shown. One set of tubes was then analysed for release of inorganic phosphate. To the other set, 5 mgm. of 'Tween-20', 20 μmoles of magnesium chloride and 1 μmole of cytidine diphosphate choline labelled with choline-1,2-^{14}C (56,000 counts/μmole/min.) were added and the incubation continued for another 2 hr. The release of inorganic phosphorus during pre-incubation (crosses) is plotted against the left-hand scale, and the synthesis of lecithin (circles) against the right-hand scale

of pre-incubation and to the prior release of inorganic orthophosphate.

These results indicate that phosphatidic acids may act as precursors of D-α,β-diglycerides *in vivo* and thus furnish the glyceride moiety of glycerophosphatides, and also show that the biosynthesis of phospholipids and neutral fats are intimately related processes.

Polynucleotide Phosphorylysis and Synthesis by Lysed Cells of *Micrococcus lysodeikticus*

AQUEOUS extracts of *Micrococcus lysodeikticus* possess a highly active enzyme capable of polymerizing mononucleotides reversibly[1]. In addition, the bacterial ribonucleic acid is readily phosphorylysed by this enzyme in the presence of inorganic phosphate. Because of these facts, we have attempted in a few preliminary experiments to evaluate the part this enzyme system may play in modifying the properties or content of bacterial cell ribonucleic acid during lysis of the cells and extraction procedures. In these experiments we have measured the acid-insoluble and acid-soluble fractions extractable from the cells during and after lysis in *tris* buffer, phosphate buffer, and in the presence of adenosine diphosphate in *tris* buffer, all experiments at *p*H 9·5. The cells were harvested from submerged 48-hr. cultures[2] and washed three times in 0·5 per cent sodium chloride. The concentration of cells was selected empirically by choosing a value which would, after complete lysis, yield an optical density of approximately 1·0 at 260 mμ for the acid-insoluble material when dissolved in 3 ml. of *tris* solution, *p*H 8·0, 0·1 *M*.

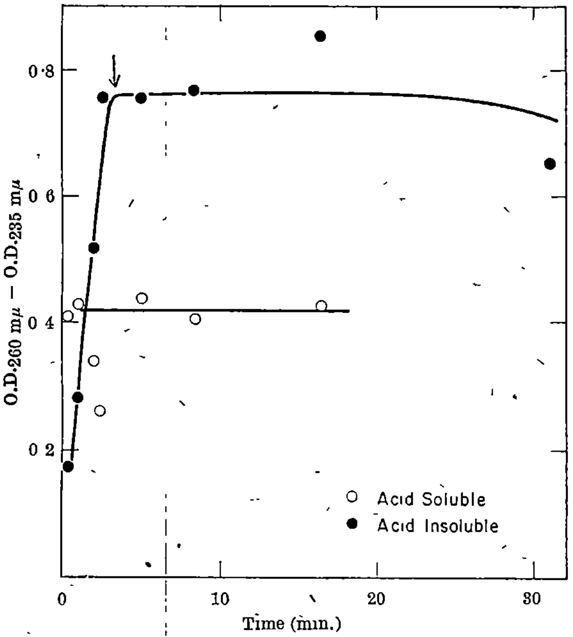

Fig. 1

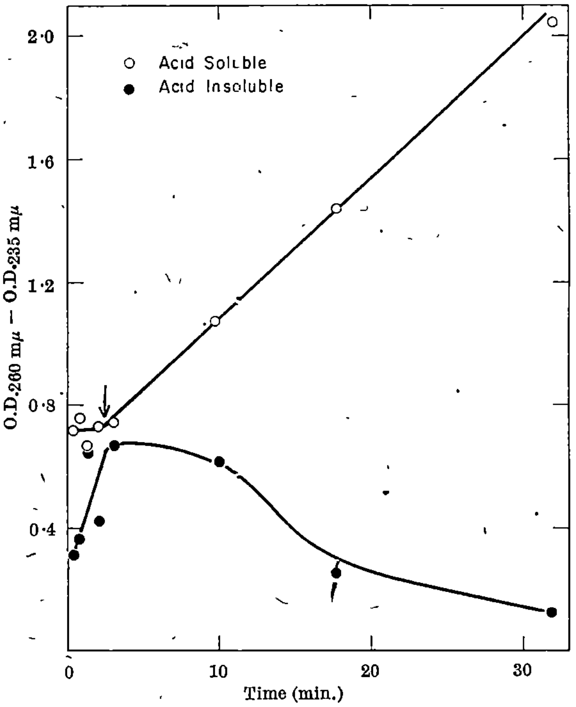

Fig. 2

In the first experiment (Fig. 1) 8 ml. of cells were mixed with 3 ml. of 0·1 *M tris* buffer and 5 ml. of 0·1 per cent lysozyme (Worthington crystalline enzyme). The suspension was incubated at 37°, and at periodic intervals 2 ml. aliquots were removed and added to 2 ml. of 5 per cent perchloric acid. The resulting precipitate and lysed cells were centrifuged down and the optical density of the supernatant measured at 235 mμ and 260 mμ. The sediment was washed once with 5 per cent perchloric acid, twice with 95 per cent ethanol, and finally dissolved in the *tris* buffer at *p*H 8·0. The optical densities were recorded as above. Plotted in Fig. 1 are the differences in optical densities at 235 mμ and 260 mμ, corrected for a 3-ml. sample. We observe that except for some scatter the acid-soluble fraction remains constant. The acid-insoluble fraction increases linearly until lysis is complete (vertical arrow), at which point this fraction, too, remains constant. The sensitivity of the method employed has not been developed to the point where we might detect transient changes in the acid-soluble fraction during the initial period of lysis. However, in view of the fact that the acid-soluble material is apparently easily extracted from intact cells, we do have a reliable indicator of any change in the concentration of the acid-soluble material should it occur. The linearity of the acid-insoluble curve suggests that the rate of lysis of the cells may be easily measured by this technique.

In the second experiment (Fig. 2) *tris* buffer was replaced by dipotassium phosphate. We observe

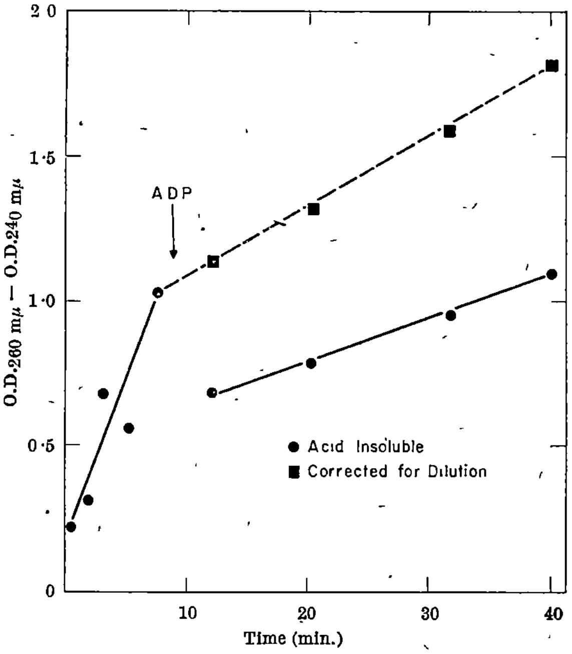

Fig. 3

the same initial increase in acid-insoluble material followed by a rapid drop. The acid-soluble material, after an initial lag, shows a remarkably linear increase. This experiment clearly demonstrates the phosphorylysis action of the lysed cells.

In the third experiment (Fig. 3) 4 ml. of cells were mixed with 2 ml. of *tris* buffer, 1 ml. of $6 \times 10^{-3} M$ magnesium chloride, and 1 ml. of 0·1 per cent lysozyme. 1-ml. aliquots were removed, added to 2 ml. of 5 per cent perchloric acid and the acid-insoluble material was determined as above. In this instance the differences at 240 mμ and 260 mμ were recorded. After 10 min., lysis was complete. 2 ml. of $10^{-2} M$ adenosine diphosphate were added. Additional 1-ml. aliquots were removed and measured for acid-insoluble material. In Fig. 3 we observe first the rapid increase in acid-insoluble material followed by a drop after dilution with adenosine diphosphate and a linear increase thereafter. The rate corrected for dilution effects is also given. This experiment clearly demonstrates the polymerase action of the lysed cells. Indeed, the rate of synthesis by unfractionated lysed cells is sufficiently great to permit one to assay the cells for enzyme content using the previously described method of assay[1].

The relationship of these findings to the *in vivo* status of ribonucleic acid is not clearly defined by these experiments. We may state that possibly the ribonucleic acid of the intact cell exists in an equilibrium with the inorganic phosphate and diphosphate mononucleotides as it certainly does in the lysed cell. However, a very difficult practical problem is suggested by these findings. The presence of an easily displaced equilibrium in the lysed cells indicates a high turnover of ribonucleic acid and mononucleotides. In other words, although the amount of ribonucleic acid and mononucleotides as indicated in Fig. 1 may remain constant, the exchange between the mononucleotides and nucleic acid may be very large, particularly if the enzyme system is very active. Therefore, the specific structure of the ribonucleic acid may vary from moment to moment, the size of the nucleic acid molecules may decrease or increase, and, in general, the state of ribonucleic acid after lysis of the cell may bear no relationship to what actually exists in the cell. The remarks can also apply to ribonucleic acid isolated from other bacteria and yeast. We conclude, therefore, that such parameters as molecular weight, mononucleotide sequence, and *in vitro* determinations of amounts of ribonucleic acid extracted from bacteria and yeast can have no important biological significance unless one has carefully ruled out the role of polynucleotide phosphorylase in the procedures adopted for disrupting the cell walls and extracting the nucleic acid.

This investigation was performed in the Division of Biochemistry, Massachusetts Institute of Technology, Cambridge, Mass., and was supported by Research Grant C-2550(*C*) from the National Cancer Institute, National Institutes of Health, U.S. Public Health Service. I wish to thank Mrs. G. Olson for her assistance in these studies.

Peroxide Formation in Bacteriological Media

It has been observed that small inocula of *Mycobacterium tuberculosis* grow poorly in synthetic media unless certain additions (serum fractions, hæmoglobin, cobalt, charcoal) all of which are peroxide-destroying agents are made. Highly isoniazid-resistant strains of *M. tuberculosis* (which are much more sensitive to hydrogen peroxide than isoniazid-sensitive strains) show a greater demand for such peroxide destroyers, especially when manganese is present in the medium[1]. Consequently, it has been suggested that these media contain traces of peroxide, although this had not been confirmed chemically.

We have examined Proskauer and Beck-type media and have shown that, as prepared in these laboratories, they contain 1–10 μgm./ml. of hydrogen peroxide. All the media investigated contained citrate. When citrate is autoclaved with manganese salts, substantial quantities of hydrogen peroxide are formed. For example, a 0·25 per cent solution of sodium citrate in phosphate buffer, *p*H 7, containing 1 μgm./ml. manganese (added as manganous chloride), autoclaved at 10 lb. for 10 min., contained about 7 μgm./ml. hydrogen peroxide. No peroxide was produced in the absence of manganese; but exceedingly small concentrations of manganese were effective. Thus about 1 μgm./ml. hydrogen peroxide was formed when 0·01 μgm./ml. manganese was autoclaved with citrate under the above conditions. Such traces of manganese were usually present in the asparagine used in these media, but occasionally were present in other constituents also.

No measurable peroxide production was observed from manganese and citrate at room temperature; at 37°, peroxide was formed slowly. A 0·25 per cent solution of sodium citrate produced 1·5 μgm./ml. hydrogen peroxide when incubated with 1 μgm./ml. manganese for three days at 37°.

The presence of peroxide was shown by liberation of iodine from potassium iodide, reaction with potassium permanganate, oxidation of benzidine in the presence of peroxidase, luminescence with luminol, and formation of 'pertitanic acid' with titanic sulphate. The last method was usually employed for quantitative determination. We did not show for certain that the peroxide formed was hydrogen peroxide; but peroxide-destroying agents of widely different type and activity—hæmin, serum, cobaltous ions, cupric ions, ferrous and ferric iron, activated carbon, Adams catalyst, sodium hydrosulphite, reductone, pyruvic acid, ascorbic acid and cysteine—all removed this peroxide from media at the same rate as they removed added hydrogen peroxide.

Hydrogen peroxide is very stable in Proskauer and Beck-type media. In glycerol-buffer it is rapidly destroyed; but citrate or asparagine greatly reduces the rate of destruction, so that in the full medium hydrogen peroxide has a half-life of more than a month, when kept at room temperature.

It has been known for a long time that light can bring about the formation of peroxide in certain other bacteriological media[2,3]. Light is not necessary for its formation from citrate and manganese, however. The mechanism involved resembles rather the well-known phenomenon of 'autoxidation', by which certain substances in the presence of oxygen and water produce hydrogen peroxide. Classical examples are the oxidation of phosphorus, lead, zinc and turpentine, while there are references also to hydrogen peroxide production from isoniazid[4], hydrazine, ascorbic acid and some heterocyclic substances.

Peroxide formation thus appears to require a reducing system which will transfer hydrogen atoms (or electrons) to oxygen. With many reducing agents the peroxide formed would be further reduced to water. In some cases, however, this further reduction does not take place, or takes place more slowly than the peroxide is formed, so that peroxide accumulates. Citrate is not readily oxidized, and requires manganese as a catalyst and raised temperatures before it reduces oxygen to hydrogen peroxide.

A wide range of other reducing agents has been investigated for ability to produce peroxide when autoclaved in the presence of manganese. Although quite a number of substances produced very small traces of peroxide, only reducing sugars and some hydrazine derivatives gave levels comparable to those obtained with citrate. Some hydrazine derivatives were particularly strong peroxide formers with manganese at 37°—thus more than 200 μgm./ml. hydrogen peroxide could be obtained with isoniazid (conc. = 2 mgm./ml.).

The formation of peroxide from citrate appeared to be catalysed specifically by manganese. Silver, aluminium, arsenic, boron, barium, calcium, cobalt, chromium, copper, iron, mercury, magnesium, nickel, chromium, lead, tin and zinc under similar conditions failed to give measurable peroxide production when autoclaved with citrate. However, the possibility cannot be excluded that there are reducing systems with which metal ions other than manganese will function catalytically, leading to the formation of peroxide. Such reducing systems may be operative in the formation of hydrogen peroxide in types of media other than those which we have investigated. For example, cuprous salts (or metallic copper) will form traces of peroxide in the presence of water and oxygen—though this peroxide does not accumulate owing to the further action of copper salts in catalytically destroying hydrogen peroxide. But these traces may explain the results of O'Meara and Macsween[5] on the effect of small amounts of copper salts on the growth of a number of pathogens. It would appear that when copper was added to their peptone media, cuprous salts were formed during sterilization, which on exposure to air formed hydrogen peroxide, thus inhibiting the growth of the inocula.

It is interesting to note that Seigel and Galston[6] have shown that manganese stimulates the formation of peroxide in plant tissues, and have suggested that if the same phenomenon occurs in bacteria it may explain the mutagenic effect of manganese on them.

Grateful acknowledgment is made to Prof. R. A. Q. O'Meara for stimulating discussions, and to Arthur Guinness, Son and Co. (Dublin), Ltd., for financial assistance.

Nucleic Acid Turnover Studies in Human Leukæmic Cells and the Function of Lymphocytes

THE experiments described here were undertaken to ascertain the pattern of purine utilization and turnover in the nucleic acids of different types of leukæmic leucocytes. The results indicate that leukæmic lymphocytes survive longer than leukæmic granulocytes. The results also direct attention to the possibility of re-utilization of large fragments of nucleic acids by lymphocytes, and invite speculation on the significance of this process as an explanation of the problem in long-term immunity of how formation of antibody continues long after the limited contact between tissues and antigen.

Adenine-8-carbon-14 (200 μc.) was given intravenously once to two patients having chronic lymphatic and to two having chronic granulocytic leukæmia; in the lymphatic leukæmia patients the predominant cell type was the small-lymphocyte and in the granulocytic leukæmia patients the leucocytes were polymorphonuclears. Pentose nucleic acid and deoxyribose nucleic acid were isolated from leucocytes collected afterwards. In leucocytes from the first two patients the radioactivities of the separated individual purines were determined, and, for the other patients, the radioactivities of the pentose nucleic acid purine nucleotides and of the deoxyribose nucleic acid purines.

Representative data on the incorporation of adenine into deoxyribose nucleic acid purines of granulocytes and lymphocytes are shown in Fig. 1; for simplicity, data on pentose nucleic acid are not shown in the figure but will be described in the text.

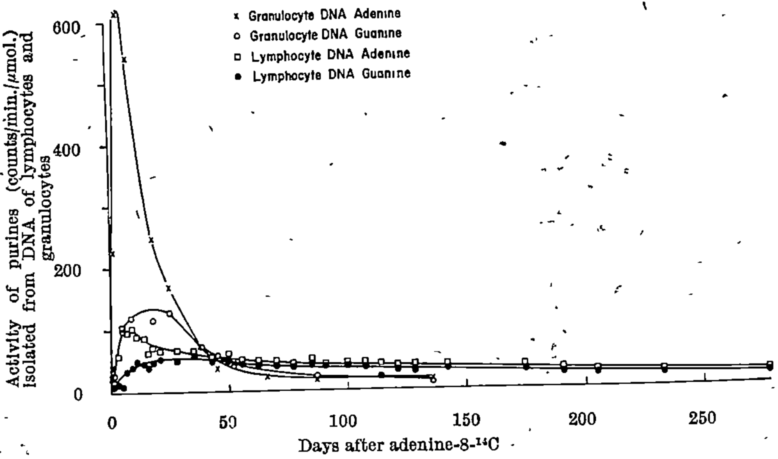

Fig. 1. Incorporation of adenine-8-^{14}C into DNA lymphocytes and granulocytes in chronic lymphatic and granulocytic leukæmia

In granulocytes, adenine as such was incorporated into deoxyribose nucleic acid; there was also extensive transformation of adenine into deoxyribose nucleic acid guanine. The curves of incorporation and transformation of adenine into polynucleotides of pentose nucleic acid and deoxyribose nucleic acid as a function of time were similar; as were also the retentions of isotope in the adenine and guanine of pentose nucleic acid and deoxyribose nucleic acid. A similarity of incorporation and turnover in pentose nucleic acid and deoxyribose nucleic acid of granulocytes is also found in intestine and bone-marrow—all of which are rapidly dividing tissues.

In lymphocytes, the incorporation of adenine into pentose nucleic acid and its transformation into pentose nucleic acid guanine resembled that in granulocytes (that is, the early portions of the curves were similar to granulocyte deoxyribose nucleic acid adenine and guanine); in contrast, the incorporation of adenine into deoxyribose nucleic acid and transformation of adenine into deoxyribose nucleic acid guanine were less extensive than the incorporation and transformation of adenine into pentose nucleic acid. In lymphocytes, then, contrary to much present belief, the lesser metabolic activity, as deduced from turnover data of deoxyribose nucleic acid compared with pentose nucleic acid, is characteristic of slowly dividing tissues such as liver.

In contrast to granulocytes, in which significant radioactivity was not demonstrated beyond 140 days, there was prolonged retention of isotope in both pentose nucleic acid and deoxyribose nucleic acid of lymphocytes; radioactivities in the deoxyribose nucleic acid purines gradually surpassed those in pentose nucleic acid. Although the initial portions of the pentose nucleic acid curves in lymphocytes were similar to the initial portions of the deoxyribose nucleic acid curves for granulocytes, in their later portions, as mentioned, they resembled the deoxyribose nucleic acid curves for lymphocytes.

The decline in activities of both pentose nucleic acid and deoxyribose nucleic acid purines of lymphocytes fell into two phases: an initial rapid decline, followed by a slow decline having a half-time of the order of 300 days.

The results suggest that the survival time of leukæmic granulocytes is less than that of leukæmic lymphocytes. If the assumption is made that deoxyribose nucleic acid once formed in a cell is stable for the life of that cell, analyses of the deoxyribose nucleic acid data permit calculations of the average survival time of each cell type (for example, by the solution of the Volterra integral equation of the first kind); this procedure is analogous to that used by Shemin and Rittenberg for the life-span of the red cell[1]. It was thus estimated that leukæmic granulocytes survive on the average for 23 days, and calculations based on the first part of the lymphocyte curves give an average survival time for leukæmic lymphocytes of 85 days. The present evidence does not permit decision whether the prolonged retention of isotope in the pentose nucleic acid and deoxyribose nucleic acid of lymphocytes (and not found in granulocytes) represents the survival of some cells for very long periods, or a specific re-utilization by lymphocytes of large fragments of nucleic acid or nucleoproteins of their progenitors.

Other kinds of evidence are in favour of the second interpretation. The phagocytosis of lymphocytes by reticulum cells in lymph nodes and the differentiation of these reticulum cells into new lymphocytes have been repeatedly observed[2]; cells have been described that are intermediate between these reticulum cells and large lymphocytes which still contain pyknotic fragments of lymphocyte nuclei (personal communications from Trowell, O. A., and from Dempsey, E. W.). Such observations suggest that there is re-utilization of large fragments of lymphocyte nucleic acids or nucleoproteins by phagocytosis.

Recognition that lymphatic tissue is an important site of protein synthesis—as indicated by antibody production—has been obscured by an inability to differentiate between the roles of lymph nodes and of the mature lymphocyte. The mature lymphocyte is little more than a nucleus, and this fact plus the re-utilization of lymphocytes by phagocytosis suggest that lymphocytes may function primarily as a store of deoxyribose nucleic acids. This hypothesis would afford an explanation of the ability to transfer immune reactions by the use of lymph nodes or lymphocytes[3]. Exposure of the embryo to antigens might result in the loss of specific deoxyribose nucleic acids responsible for the production of homologous antibodies, possibly by an absence of the conservation mechanism of phagocytosis and re-utilization in the embryo; the adult exposed as an embryo to an antigen would thus have lost the ability to respond[4]. Since antibodies are incapable of self-replication in later life[5], the process of phagocytosis with re-utilization of nucleic acids allows for the selective preservation of necessary templates for the production of specific antibodies, and might account for the continued formation of antibody long after the apparently limited contact between tissues and antigen. A fuller account of these studies will be published elsewhere[6].

I wish to thank Dr. C. C. Stock for encouragement and facilities, Dr. G. B. Brown, Dr. M. E. Balis and Dr. A. Bendich for helpful advice about technical methods leading to this work, Dr. S. Schuster and Mr. M. Berman for much discussion and assistance in the mathematical analyses, Dr. M. E. Balis for supplying part of the adenine-14-carbon, and the Chemotherapy Service, Memorial Center, for their co-operation. The work has been aided by grants from the National Cancer Institute of the United Public Health Service C-1813 and from the Commonwealth Fund.

Proteolytic Enzymes in *Entamoeba histolytica*

THE presence of proteolytic enzymes in *Entamoeba histolytica* has been suspected for many years and he extracellular secretion of these enzymes has been put forward by many authors as an explanation of the mechanism of tissue invasion by this parasite[1]. Experimental evidence of their occurrence in *E. histolytica* has been presented by several authors[2], though a detailed study of them has not been made.

The proteolytic enzymes of *E. histolytica* (strain $P + A^1$) were investigated by making an extract of amoebae grown *in vitro* in association with *Escherichia oli*. The amoebae were collected in suspension from the culture medium (solid egg base covered with dilute horse serum, supplemented with rice starch) and washed with Tyrode solution. The amoebae were re-suspended in a volume of Sørenson's phosphate buffer, pH 7·2, to give a calculated concentration of 5 million amoebae/ml. The amoebae were then frozen overnight. After thawing, the rice starch and debris were removed by centrifuging and the supernatant was shaken with a few drops of chloroform to inhibit the growth of bacteria. Excess chloroform was removed by centrifuging. Extracts prepared in this manner from strain $P + A^1$ were sterile.

The extract was incubated at 37° C. with casein olution as substrate and with ammonia – citric acid buffer to give a range of pH from 4·0 to 8·5. After ncubation, the reaction was stopped by the addition of trichloracetic acid. The degree of hydrolysis of the casein was determined with Folin–Ciocalteau phenol reagent, and expressed as μgm./ml. of tyrosine. The method is similar to that described by Holter and Løvtrup[3].

The extract showed high activity from pH 6·5 to 8·5 with a maximum at pH 7·9–8·0. When the extract was incubated with the substrate at the optimum pH, the amount of hydrolysis increased linearly with time up to the end of 2 hr.; thereafter he rate of hydrolysis decreased. The activity was not potentiated by cysteine or inhibited by iodoacetate.

The proteolytic enzymes in extracts of strain $P + A^1$ also dissolved formalin-denatured gelatine and reduced the viscosity of gelatine solutions.

Extracts of the associated strain of bacteria, *Escherichia coli*, showed no proteolytic activity on the casein substrate, nor did they affect the viscosity of gelatine solutions.

Other strains of *E. histolytica* are being examined by this technique and all show some proteolytic activity. Further details of experiments showing the correlation of virulence and proteolytic activity will be published elsewhere.

Disomic and Tetrasomic Inheritance in a *Solanum* Hybrid

IN the course of a cytogenetic study of the nature of differentiation of diploid species ($2n = 24$) of the section Tuberarium, genus *Solanum*, the mode of inheritance of three loci could be followed in a cross between *S. macolae* and *S. simplicifolium*, two species of the series Tuberosa occurring in Bolivia and Argentina. The *simplicifolium* parent used in the cross had simple leaves, a prominently winged stem and white corolla, in contrast to the compound leaves, rudimentary stem wing and purple corolla possessed by the *macolae* parent. Except for corolla colour in *macolae*, the two species bred true for their characters. The *macolae* parent was found to be heterozygous for P, a dominant factor necessary for the formation of purple colour in the corolla.

Meiosis was regular in the F_1 plants, and the plants set berries with viable seeds. These plants had compound leaves and prominently winged stems. There was segregation for corolla colour; six plants had purple and four plants had white corollas. In F_2 progenies from F_1 plants with compound leaves, prominent stem wing and purple corolla, there was monogenic segregation for all the characters. In backcrosses between the F_1 and recessive and dominant parents, 1 : 1 and ∞ : 0 segregations respectively were obtained. Thus, the genotypes of the *macolae* and *simplicifolium* parents were determined as $LLwwPp$ and $llWWpp$ (L, for compound leaf; W, for prominent stem wing and P, for purple corolla) respectively. There was no evidence of linkage among factors L, P and W in the F_2 and backcross data.

Seeds from the initial cross were treated with colchicine, and tetraploid hybrid plants were thus obtained. At first metaphase in the doubled hybrid, there was a mean frequency of 1·19 quadrivalents 0·095 trivalents, 21·025 bivalents and 0·905 univalents per cell. The number of quadrivalents per cell ranged from 0 to 4. The tetraploid plants were fertile. When the C_2, C_3 and C_4 plants (corresponding to the F_2, F_3 and F_4 plants of the diploid hybrid) were grown in following years, it was found that all

Table 1. INHERITANCE OF LEAF-TYPE IN *S. macolae* × *S. simplicifolium*

Material	Genotype	Segregation				Deviation	
		Observed		Expected			
		L	*l*	*L*	*l*	X^2	*P*

C_3 progenies i. C_2 206 self	*Llll*	18	4	3	1	0·5454	0 5–0 3
ii. C_2 203 × 205	several possibilities	132	0	*X*	0		
iii. C_2 211 (compound) × C_2 198 (simple)	*LLll* × *llll*	73	19	5	1	1·0464	0·4–0·3
iv. C_2 198 self	*llll*	0	28	0	*X*		
C_4 progeny	*LLll*	39	1	35	1	0 0112	0·95–0·9

the plants in the different generations had broad stem wings like the C_1 and *simplicifolium* parents. Since the C_1 plants would have had the genotype *WWww* for stem wing character, the lack of segregation in subsequent generations would mean that the *simplicifolium* chromosomes carrying factor *W* were pairing preferentially at the tetraploid level. The segregation ratios for leaf type, however, were typical of tetrasomic inheritance; simplex and duplex genotypes were identified by the 3 : 1 and 35 : 1 ratios obtained on selfing C_2 plants (see Table 1) and a 5 : 1 ratio was observed on backcrossing a duplex to a nulliplex type. The chromosome numbers of the simple leaf plants in C_2, C_3 and C_4 were determined to make sure that the simple leaf character in them is not due to the loss of chromosomes carrying the *L* factor. The number in all the plants was $2n = 48$, and it is thus clear that the locus *L* in tetraploid *macolae* × *simplicifolium* segregates tetrasomically.

For colchicine treatment, seeds from the initial cross-had been used, and consequently there was segregation for corolla colour in the C_1 plants (three coloured and two white). In the C_2 progeny grown from a sib-cross between two C_1 plants, one with coloured and another with white flowers, the forty-three plants which flowered all had coloured corollas. Two C_3 progenies were raised: one from seeds of a C_2 plant selfed and another from a C_2 sib-cross. Both segregated for corolla colour in the ratio 3 coloured : 1 white (observed: 29 : 11 and 12 : 5 respectively). The genotypes of the C_1 plants with purple and white corollas would be *PPpp* and *pppp* respectively, and the ratios suggest that the chromosomes in which the *P* locus is situated pair preferentially at the tetraploid level. From the data concerning the inheritance of factors *L*, *W* and *P* in the diploid and tetraploid populations of *macolae* × *simplicifolium*, it can be concluded that the quadrivalents and bivalents observed in the tetraploid are not formed in a random manner but result from pairing among specific chromosomes. These observations thus lend support to the inference drawn earlier from cytological studies[1] that cryptic structural differentiation of chromosomes has played an important part in the origin of species differences in the section Tuberarium.

Chelating Agents as Growth Substances

SINCE the article[1] under the above title wa published, we have obtained further biologic evidence bearing on the mode of action of auxi We carried out two root-growth experiments exactl similar to those of 23.3.56 and 21.4.56 (Tables 4 and *loc. cit.*) but using 8-hydroxyquinoline and ethylenediaminetetra-acetate instead of 3-indolylacetic aci and ethylenediaminetetra-acetate. Essentially simila results were obtained, that is, the inhibition of ro growth caused by 10^{-5} *M* 8-hydroxyquinoline o 10^{-5} *M* ethylenediaminetetra-acetate alone was largel prevented by the presence of 10^{-11} *M* ethylenediaminetetra-acetate in the former case or of 10^{-11} 8-hydroxyquinoline in the latter.

In a further similar root-growth experimen 2-hydroxyquinoline, a non-chelating analogue o 8-hydroxyquinoline, and ethylenediaminetetra-acetat were used. Again, a most remarkable interactio was obtained; but the roles of the two substance were no longer mutually interchangeable. Thus th inhibition due to 10^{-5} *M* ethylenediaminetetra-acetate alone was considerably less in presence o 10^{-11} *M* 2-hydroxyquinoline; but the rather sma amount of inhibition caused by 10^{-5} *M* 2-hydroxyquinoline alone was made very much more sever by 10^{-11} *M* ethylenediaminetetra-acetate.

We have also extended the investigation of th growth responses of coleoptile sections to includ supraoptimal concentrations of the agents, and so fa the picture is essentially like that for inhibition o root growth in intact plants. Using concentration of zero, 10^{-9}, 10^{-7}, 10^{-5} and 10^{-3} *M*, we have foun with 3-indolylacetic acid and ethylenediaminetetra-acetate that a 10^{-9} *M* concentration of either agen greatly reduces or prevents the inhibitory or harmf effect of a 10^{-3} *M* concentration of the other. (A intermediate concentrations significant stimulation o course occurs, unlike the root-growth results.) Th same type of mutual antagonism has been found in similar experiment using 3-indolylacetic acid an 8-hydroxyquinoline and also in another using th latter and ethylenediaminetetra-acetate. Wit 2-hydroxyquinoline and ethylenediaminetetra-acetat the former shows only inhibitory effects; 10^{-9} 2-hydroxyquinoline slightly increases the inhibitio due to 10^{-3} *M* ethylenediaminetetra-acetate, wherea 10^{-9} *M* of this agent to some extent removes the harmful effect of 10^{-3} *M* 2-hydroxyquinoline. Here th roles of the two agents are reversed as compare with their effects on root growth (see above). Wit 2-hydroxyquinoline and 3-indolylacetic acid, th former again shows inhibitory effects throughou but either agent at 10^{-9} *M* shows a small tendenc to increase the inhibition due to a 10^{-3} *M* concentration of the other. (Two out of three roo growth experiments which were carried out usin these two agents, at the usual concentrations zero and 10^{-11} to 10^{-5} *M*, also showed no tendenc for a 10^{-11} *M* concentration of one to prevent the inhibition caused by a 10^{-5} *M* concentration of the other; the third experiment gave an aberrant result.)

Table 2. Effect of Pre-drying after Harvest on the Percentage Germination

Treatment	No. of samples grouped according to percentage germination									
	0–10	11–20	21–30	31–40	41–50	51–60	61–70	71–80	81–90	91–100
10 days at 16°–18° C.	—	1	2	3	17	10	8	10	11	—
and 3 days at 40° C. 7 days at 16°–18° C.	—	—	—	—	—	—	—	1	4	57

The extraordinary mutual antagonism described has in fact always been found (and, with the exception of the single aberrant experiment mentioned, only been found) in experiments with two known chelating agents or with 3-indolylacetic acid and a known chelating agent; the substitution of a non-chelating analogue for one of the agents destroys the symmetry of the interaction or entirely prevents either agent at low concentration from reducing the inhibition caused by a high concentration of the other. The fact that 3-indolylacetic acid interacts with known chelating agents in the same remarkable and symmetrical way as these interact with each other in affecting the growth of roots and of coleoptile sections would seem strongly to support the hypothesis that it is here itself acting as a chelating or complex-forming agent. On this hypothesis, however, there is no reason why 3-indolylacetic acid should interact with the non-chelating 2-hydroxyquinoline in the same way as does ethylenediaminetetra-acetate if the latter interaction is not due to chelation.

Although the biological evidence for chelation or complex-formation by 3-indolylacetic acid appears to us convincing, we have not so far been successful in attempts to obtain direct chemical evidence. The difficulty experienced here may perhaps be due to 3-indolylacetic acid only forming complexes with one or a few metals and (or) within a narrow range of conditions; this might well be biologically advantageous to the plant.

Effect of Desiccation on the Dormancy of Barley

In certain seasons the condition of dormancy in barley is prolonged and the delayed germination of a proportion of the grains has an adverse effect on its use for malting[1]. Observations over a number of years have indicated that this condition is more marked when atmospheric humidity is high before harvest. The effect of desiccation has therefore been investigated, as it is also an important factor in the maturation of wheat[2]. During ripening, transfer of material to the endosperm ceases at a moisture content of about 42 per cent, and the grain then undergoes rapid drying[3]. The final moisture content is determined, however, by the atmospheric humidity and the degree of desiccation therefore depends on the weather conditions before harvest.

Table 1. Effect of Desiccation on Percentage Germination, (*a*) During Ripening, and (*b*) at the Harvest-ripe Stage

Moisture content (per cent fresh weight)		Percentage germination After 10 days at 16°–18° C.	After 3 days at 40° C. and 7 days at 16°–18° C.
(*a*)	40–45	6	95
	29–35	10	94
	16–20	44	96
(*b*)	17·4	44	99
	18·1	72	99
	16·9	82	100
	12·7	99	—

The percentage germination was determined at intervals during the final stages of ripening by removing undamaged grains from the ear and placing them either directly in damp sterile sand, at 16°–18° C. for ten days, or after pre-drying for three days at 40° C., which reduced the moisture content to 7 per cent.

The effects of natural and artificial desiccation are shown in Table 1. About half the grains acquired ability to germinate as soon as the moisture content fell during ripening from 40 to 16 per cent, and the majority of the remainder did so later without any further desiccation. Complete germination did not, however, take place until atmospheric conditions allowed the moisture content to fall to 12·7 per cent, although it was obtained after pre-drying at each stage. Full maturity was thus eventually attained by natural desiccation, and although individual grains differed in their response to the same degree of desiccation at the harvest-ripe stage, these differences were removed by additional desiccation. There was no evidence that the dormant condition developed at the time of harvest, as suggested by Bishop[4].

When the dormant condition persists after harvest, it can also be successfully eliminated by additional desiccation. This is shown, in Table 2, by the increased germination after pre-drying obtained with sixty-two samples of commercial malting barley tested between August and October 1954.

It therefore appears that a varying proportion of grains may fail to reach maturity because of insufficient desiccation before harvest; but this can be corrected by artificial drying during subsequent storage.

An Instance of Delayed Communication in Solitary Wasps

The eumenid *Rygchium foraminatum* (de Saussure) and the sphecid *Trypoxylon clavatum* Say are common solitary hunting wasps which nest in hollow twigs, making the burrows septate with cross-walls of mortar so that a linear chain of cells is formed. Each brood cell, when first made, contains a single egg along with paralysed prey sufficient for full growth of the young hatched larva to the adult wasp. Generally the provisioned cell is only somewhat larger than the wasp which will mature within it, and indeed may be too small in diameter to permit the adult wasp, once formed, to reverse its direction within it. The oldest wasp larva of necessity lies innermost at the blind end of the burrow, while the youngest occupies the cell nearest the sole exit from the nest. When nests are constructed in burrows 4–6 mm. in diameter and 150 mm. long, each mother wasp may provision from 1–10 cells per burrow, most nests having 4–6 provisioned cells.

If a nest is split lengthwise after feeding, cocooning and pupation are completed, the pupæ which lie lengthwise in their cells are regularly found to face the sole exit of the nest. Orientation of a pupa toward the blind end of the burrow occurs, but is relatively rare and has serious consequences—especially in nests with minimal diameters. Ordinarily, emergence from linear nests is in reverse order to actual age, so that the wasp from the last egg to be laid is first to emerge from the nest, the next youngest wasp second to emerge, and so on. Misoriented wasps work their way, when they can do so, to the blind end of the burrow, generally resulting in the death of sibs older than themselves, and almost invariably in their own death as well. On the average, then, if misorientation is rare and random with respect to cell order, reversal of a single pupated wasp may be expected to result in the death of more than one nest occupant.

Since larvæ within their cells neither have nor can attain direct knowledge of the location of the exit from the burrow, and since larvæ may take any position within their cells during feeding, a highly efficient substitute for direct knowledge must be provided in the nest. Experiments have shown that the location of the egg, disposition of prey, possible asymmetric marking of the cell by the occipital glands of the mother, gaseous diffusion, and so on, at most play negligible parts so far as orientation of the larvæ at pupation is concerned. But if each cell's mud walls are reversed in position by rotation 180° about a diameter, care being taken to minimize breakage, then the enclosed larvæ pupate in reversed direction, that is, facing the blind end of the burrow.

The information acted upon by each pupating larva lies in the geometry and texture of the surfaces of the anterior and posterior cell walls. It can be shown that the information provided is redundant. A scanning comparison of two surfaces is not necessary to bias markedly the orientation of a pupating larva, nor indeed is a natural cell-wall necessary. A sandpaper disk placed transversely across a burrow, for example, is adequate to cause a larva to pupate facing the grit in the preponderance of cases. Furthermore, *Trypoxylon* larvæ, transferred to *Rygchium* nests, and vice versa, pupate with correct orientation toward the exit of the foreign nest. The informational signals of these remotely related wasps are thus similar.

The female wasp makes these cell walls asymmetric in relation to the nest's sole exit. In turn the larva responds to the asymmetry by orienting towards the nest's exit on entering the pupal state. In effect the mother wasp acts as an information source and transmitter, the mortar of the cell wall serves as a communication channel, and the geometry and texture of the walls as signals. The information is stored, then, in digital form in an artefact. The receiver and destination of the message is the fully fed larva, the highly regular response of which is in turn a measure of the singular effectiveness of the communication system.

Haldane and Spurway[1] and Haldane[2] have given analytical and interpretive summary accounts of animal communication that should do much to enliven research and discussion of this topic. The wasps discussed above provide a new and novel example of animal communication, for not only is the signal produced within a complete artefact, but also the stored signal serves as a message between parent and young, members of two generations that ordinarily do not overlap in contact. A detailed account of this work will be published elsewhere.

Regenerative Capacity of Tadpoles inhibited in Growth and Development

As shown previously, 20-day old tadpoles of *Xenopus laevis* exhibit, after removal of the telencephalon and plexus chorioideus of the third ventricle, complete inhibition of development and almost complete cessation of growth[1]. In the course of recent experiments, we tested the regenerative capacity of these partially decerebrated experimental animals, operated on 2, 5 or 18 months before the amputation of the tail. As controls, we used tadpoles of the same length as the experimental ones. We were also able to compare regeneration in animals deprived of the telencephalon for two months with that of normal tadpoles of the same age, the development of which was delayed by the action of a lower temperature.

In spite of the inhibition of growth and development, the experimental animals retained the ability to regenerate amputated tail-tips. Whereas the first phases of the regenerative processes, that is, the covering of the wound surface with epithelial cells, proceeded at the same rate and in the same manner in experimental and in control animals, the visible regeneration of the axial organs appeared 2–3 days later in experimental tadpoles. The same result was obtained whether the tadpoles were operated on 2, 5 or even 18 months before the amputation of the tail.

In order to find out whether the inhibition of growth and development in experimental animals is in any way correlated with a decrease in mitotic activity, we determined the mitotic frequencies of the epithelial cells in mounted preparations of the tails. In every tail, we counted 6,000–10,000 cells in a series of fields, and expressed in percentages the number of dividing nuclei ranging from prophases to telophases.

In control animals, on the average, 1·3 per cent of mitotic nuclei were found, while two months after operation 0·4 per cent and 18 months after decerebration only 0·1 per cent mitotic nuclei were present. It seems, therefore, that the inhibition in growth observed in tadpoles after the excision of the telencephalon and plexus chorioideus on the twentieth day after hatching is due to a decrease in mitotic activity.

If, however, in inhibited tadpoles the tail tip is amputated and the regenerative processes set up, the number of dividing cells increases. Six days after amputation of the tail, we found 0·8 per cent of dividing nuclei in tadpoles decerebrated two months before amputation. A similar increase was observed in regenerating animals operated on five months before amputation. The increased number of dividing cells in regenerating experimental animals is probably induced by stimuli originating in wounded tissues after the initiation of regenerative processes. We had previously found a similar effect in regenerating tadpoles treated with nitrogen mustard[2], and Lüscher described an increase in mitotic activity on the third to the sixth day after amputation of the tail of *Xenopus laevis* tadpoles[3].

Adrenaline and Noradrenaline in Adrenal Autografts

BOTH cortical and medullary cells survive in adrenal grafts months after transplantation into the anterior chamber of the eye[1]. It is, however, not known whether the two medullary hormones, adrenaline and noradrenaline, are present in the grafts. Moreover, all previous work has been without regard to the fact that there are two different types of cells in the adrenal medulla[2]. A substantial body of evidence is now available indicating that one of these cell types contains and secretes adrenaline, and the other noradrenaline[3,4]. It seemed therefore to be of interest to investigate adrenal grafts by chemical and histochemical methods which differentiate between adrenaline and noradrenaline.

Adult Wistar rats were used. The left adrenal of each animal was removed, and a piece of the medulla was inserted into the anterior chamber of the left eye. Five months later the animals were killed and the grafts removed.

The adrenaline and noradrenaline contents of some grafts were estimated chemically after separation of these amines by ascending paper chromatography, using a mixture of phenol and 0·1 *N* hydrochloric acid[4]. Both adrenaline and noradrenaline were detected in the grafts (Fig. 1). The adrenaline content was 5–10 times the noradrenaline content.

Other grafts were plunged into a 3·5 per cent solution of potassium dichromate to produce the chromaffin reaction, or into a saturated solution of potassium iodate to demonstrate the noradrenaline-containing cells[3]. These grafts were afterwards fixed in formalin and cut with a freezing microtome at 50µ. Some sections were mounted unstained in glycerol, others were stained with hæmatoxylin and sudan red to facilitate the detection of adrenocortical cells.

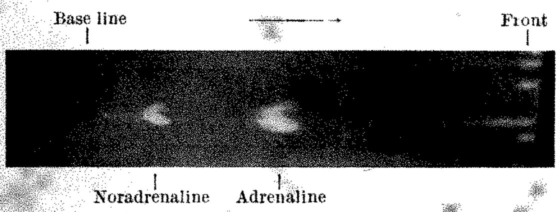

Fig. 1. Chromatogram of an adrenomedullary autograft smeared directly on the base line of the paper (Whatman No. 1). Phenol and hydrochloric acid were used for development, and the strip was sprayed with potassium ferricyanide to develop fluorescence in the adrenaline and noradrenaline spots. Fluorescence photograph

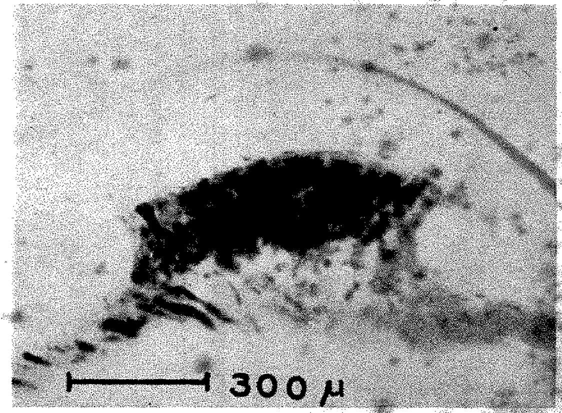

Fig. 2. Unstained frozen section of an adrenomedullary autograft in the anterior chamber of the eye. The graft is attached to the cornea (above) and the iris (below). Chromaffin cells are brown after dichromate fixation. Red blood cells in the vessels of the iris (lower left corner) are also brown

Fig. 2 shows a typical graft, mainly composed of strongly chromaffin cells, and attached to both the cornea and the iris. The chromaffin cells were closely packed together in the grafts. However, regular cell acini, such as can be always seen in the normal adrenal medulla, were replaced by irregular groups of cells. This may be indicative of cellular migration within the graft.

The iodate reaction, which stains the noradrenaline-containing cells brown[3,4], was positive in some graft cells, which were usually solitary and randomly distributed in the graft. The majority of graft cells, although chromaffin, remained colourless after iodate treatment. This is in good agreement with the chemical observations made, and suggests that the grafted adrenomedullary cells have retained their ability to make and secrete the same catechol amine which they were making and secreting in the adrenal before grafting.

Although efforts had been made to include only medullary tissue in the grafts, typical sudan-positive cortical cells were detected in all grafts which were examined histologically. The cortical cells were fewer than the medullary ones and usually apart from these. It is therefore most likely that cortical hormones were equally available to both the iodate-positive, noradrenaline-secreting cells and the adrenaline-secreting cells of the graft, in which the two types of cells were present in proportions similar to those in the normal rat's adrenal medulla. If cortical hormones really have a specific influence on the quality of the secretory products of the adrenomedullary cells, as has been claimed[5], such an influence could not be observed in the present study.

FORTHCOMING EVENTS

Wednesday, September 19

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. W. T. Lyn: "Diesel Combustion Study by Infra-Red Emission Spectroscopy".

Thursday, September 20

Oil and Colour Chemists' Association (at University College, Gower Street, London, W.C.1), at 10.30 a.m.—Symposium on "Some Implications of Colour".

Physical Society (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Prof. J. G. Daunt (Ohio State University): "The Magnetic Refrigerator for Temperatures below 1° K." (Duddell Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chemist (with a first- or good second-class honours degree in chemistry, or equivalent qualification, at least three years experience, and preferably a knowledge of liquid fuels and lubricants), at the London Transport Central Laboratory, Chiswick, London—The Recruitment and Training Officer, London Transport, 55 Broadway, London, S.W.1, quoting F/EV.597 (September 20).

Lecturer in Applied Mathematics—The Registrar, The University, Liverpool (September 20).

Senior Lecturer (with high academic and research qualifications) in Organic Chemistry, and a Lecturer (able to teach their branch of chemistry to special (honours) degree standard) in Inorganic and Physical Chemistry—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (September 21).

Assistants (3), Grade B (for physics, general chemistry and mathematics), in the Science Department, Birkenhead Technical College—The Director of Education, 63 Hamilton Square, Birkenhead (September 22).

Lecturer and Assistant Lecturer in Physics at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 29).

Lecturer or Assistant Lecturer (with special interests in general, inorganic or physical chemistry) in Chemistry—The Registrar, The University, Sheffield (September 29).

Lecturer, Grade II, in Physiology at the University College, Ibadan—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (September 29).

Federal Information Officer (with considerable experience of information service work, preferably in the Caribbean area), to plan and build up the Information Service of the Federal Government and to serve as Executive Head of the service stationed initially in Barbados—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.148/500/01 (September 30).

Lecturer (with a good degree in economics, commerce, administration or some branch of technology, with managerial experience in industry and preferably with some research experience in any of the above fields) in Industrial Administration, to deal with management subjects from a general management viewpoint and to undertake research—The Registrar, College of Science and Technology, Manchester 1 (September 30).

Junior Research Fellow, Research Fellow and Senior Research Fellow (with a good honours degree in economics and an interest in economic analysis) for the Research Staff of the Institute of Social and Economic Research, University College, West Indies, for investigations which may be made in any part of the British Caribbean territories—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 1).

Lecturer or Assistant Lecturer (with a good degree in science or applied science, and research experience in general ceramics, refractory materials or related fields, preferably with some industrial experience) in Ceramics and Refractory Materials—The Registrar, The University, Leeds 2 (October 1).

Statistician (with an honours degree in economics or commerce, able to give close attention to detail and to write clearly) in the Area Statistician's Office, Eastern Gas Board, Tottenham, London, for work concerned partly with the compilation of statistics and partly with the preparation of statistical reports for the guidance of the management—The Secretary, Eastern Gas Board, 2 The Abbey Garden, Great College Street, Westminster, London, S.W.1 (October 6).

Senior Lecturer in Aeronautical Engineering at the University of Sydney, to work in the field of aerodynamics—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 8).

Senior Lecturer or Lecturer in Physical Chemistry or Inorganic Chemistry at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 12).

Lecturer in Botany at the University of Natal—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 15).

Lecturer or Assistant Lecturer (graduate, with experience and/or special interest in surveying and tutorial mapwork) in Geography at the University of Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 15).

Lecturer or Senior Lecturer (with qualifications in economic geography) in Geography at the Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 15).

Lecturer (graduate in chemistry with a knowledge of modern synthetic resins and rubbers) in the Department of Leather Industries, to give instruction in, and to investigate the application of synthetic resins and rubbers to various leathers—The Registrar, The University, Leeds 2 (October 15).

Director of the Computing Unit—The Secretary of Faculties, University Registry, Oxford (October 30).

Lecturer or Senior Lecturer in Fluid Dynamics at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

Assistant Conservators (with a university degree in forestry) of Forests in British Guiana—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.61/30/02.

Cyclotron Engineer or Physicist (graduate in light electrical engineering or physics) at Hammersmith Hospital, to work on the cyclotron, with opportunity to gain experience in engineering mechanics including cyclotron beam measurements, high vacuum work, target design and ion sources development—The Senior Cyclotron Engineer, Medical Research Council, Hammersmith Hospital, Ducane Road, London, W.12.

Fisheries Officer (with an honours degree in natural science with emphasis on zoology, preferably with a knowledge of French and experience of work at sea and the handling of nets) for the Western Region of Nigeria, to develop inshore fishing and fish culture—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.461/410/03.

Geologist (with a first- or second-class, upper division, honours degree in geology, preferably with experience in an alluvial diamond field) with the Government of Sierra Leone, for the geological examination and mapping of the diamond deposits of Sierra Leone, together with special reference to the areas now being opened up under the Diamond Licensed Mining Scheme, to describe these areas and to prepare a report and eventually a bulletin on these deposits—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/15/01.

Graduate in Biological Science in the Department of Zoology, to assist in research on mass culture of marine algae—Professor of Zoology, The University, Southampton.

Health Physicist (with a degree in physics and some experience in nuclear physics and electronics, and an interest in biophysics, physiology or biology, preferably with a knowledge of French) with the European Organization for Nuclear Research, Geneva, to take charge of a small team entrusted with the physics measurements pertaining to all radiation protection in all CERN laboratories, and to develop measuring techniques in an unusually high energy region (up to 600 MeV. protons)—The Ministry of Labour and National Service, Employment Services Department (AS.12), 26 King Street, London, S.W.1.

Junior Scientific Officer (with an honours degree in science, pharmacy or biology), for technical work in the Blood Transfusion Service Laboratories—The Director, Blood Transfusion Service, Roby Street, Manchester 1.

Scientific Officers (3) (with first- or second-class honours degrees in civil engineering, economics or statistics, or equivalent qualification) in the Colonial Section, Road Research Laboratory, Department of Scientific and Industrial Research, for duties concerning road materials and methods of construction, soil mechanics, traffic engineering, road safety and economics of roads and road transport—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting E.384/6A.

Technician (with a good knowledge of electronics and experience in the construction and maintenance of electronic apparatus) in the Department of Applied Electrophysiology—The Secretary, The National Hospitals for Nervous Diseases, Queen Square, London, W.C.1.

Training Officer (with an engineering or science degree and training and organizing experience) in the Public Works Department, Government of Western Nigeria, to be responsible for training junior grades of a large Government Department and to correlate training facilities to ensure the fullest use is made of existing educational and technical establishments—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.112/410/018/T.

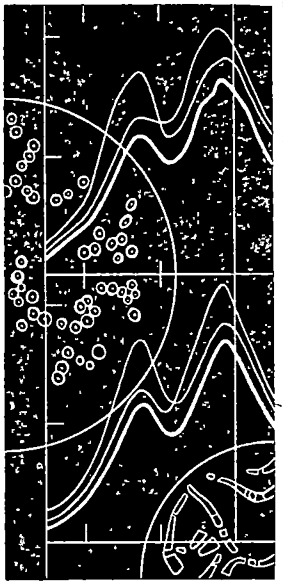
BOOKS ON SPECIALIZED SUBJECTS

Books on science, research, electronics, industrial work, electrical and mechanical engineering can be quickly supplied through your local Smith's shop or bookstall. College and works librarians and students, particularly, are invited to ask for lists of books on any subject. Any books not stocked locally will be quickly obtained from Head Office.



Your stationery and printed matter can also be supplied through our local branch.

FOR SCIENTIFIC BOOKS

Head Office: STRAND HOUSE, LONDON, W.C.2

CHARLES GRIFFIN & COMPANY LTD

THE HISTORY OF THE TELESCOPE H. C. KING Ph.D., F.R.A.S.

"The 456 pages of this excellent book are evidently the result of a truly tremendous amount of research. Dr. King deserves the highest praise."
H. E. Butler reviewing in "Nature."

"Likely to become a classic. The book is a remarkable piece of work, and in my view is the astronomy book of the year."
Dr. J. G. Porter in B.B.C. broadcast, Feb. 24, 1956.

Very fully illustrated. 10½ in. × 7½ in. 456 pages 50s. net.

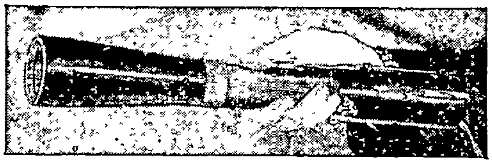
Schoeller & Powell's ANALYSIS OF MINERALS AND ORES OF THE RARER ELEMENTS A. R. POWELL F.R.I.C., F.R.S.

Contains all the newer analytical procedures including chromatography, polarography, solvent extraction, and spectrophotometry, as well as new gravimetric and volumetric methods. The chapters on uranium, scandium, rhenium, and the platinum metals have been completely rewritten, while the remaining chapters have been revised.

THIRD EDITION, Reset, 409 pages, 9 in. × 6 in. 60s. net

42 DRURY LANE LONDON WC2

THE ARROW ↑ PROJECTION TORCH



The Arrow Projection Torch is designed for use wherever teaching is accompanied by screen illustration. An arrow of high intensity illumination is projected, and may be focused to any distance from 6 to 40 feet.

A descriptive and illustrated pamphlet is available and this will be gladly sent on request.

WORLD POWER IN THE NUCLEAR AGE

WHEN the Chancellor of the Exchequer made his statement about economies in Government xpenditure on June 26, he pointed out that the aving of £36·5 million on the defence estimates did ot reflect any change in the size or shape of the rmed Services. The savings, of which about £11 illion is on the Navy estimates, nearly £17 million n the Army estimates and about £8·75 million on he Air estimates, arise mainly from abandoning or eferring orders, from increasing the use of existing ocks and from expediting the disposal of surplus ocks. Mr. Macmillan referred to the review of efence policy which the Prime Minister had underken, and gave the assurance that any major ecisions in this field would be taken only after nsultation with our allies.

This assurance, which the Prime Minister repeated the House of Commons on July 23, was needed, r the Government, as two recent debates on scientific search and on technical education have shown, is xposed to a continuous clamour to reduce expendiure on defence quite regardless of the consequences. here is, however, a further principle that needs to enunciated more clearly at a time when the overnment is being pressed with perhaps more al than foresight to reduce its expenditure on efence. If we are to get the best results in up-toate mobile joint defence at the lowest expenditure, will only be by proceeding hand in hand and step step with the United States. It is right to point t that Britain's position in the world has changed d that there are limits to the expenditure which e can wisely incur on defence—in terms of manwer, finance or economic resources; and it must recognized that changes in policy and in disposition n only be made in agreement with our allies.

It is, of course, the uncertainty as to the effect on efence of nuclear warfare that has been responsible r many dubious proposals, and such books as dmiral Elis Biörklund's "International Atomic licy during a Decade, 1945–1955"* and Prof. E. W. tterton's "Facing the Atomic Future"†, are inluable in promoting public understanding of the nitations, as well as of the dangers, of nuclear arfare. Moreover, the *Bulletin of the Atomic ientists*, which has initiated a symposium on Science and the Affairs of Man" to continue through t the tenth anniversary year of the *Bulletin*, after article in the April issue by R. Aron, discussing e possibility of half a century of limited war, has voted its May and June issues to a special discussion science and military strategy.

Admiral Biörklund reviews the decade in two ctions, the second of which is concerned essentially with the hydrogen bomb. Then he attempts, in two successive chapters, appreciations of the views of the Western Powers and the Eastern Powers on problems which nuclear weapons present, before considering briefly the technical development of such weapons. His own conclusions as to the possibility of international control are set forth in the following chapters, and the most important of these conclusions is the rejection of the theory, with which he started, that all nuclear weapons should be controlled. He now believes that the manufacture of nuclear weapons could never be effectively controlled, and that they should accordingly be ignored from this point of view and included with conventional armaments. Further, he insists on the importance of restricting control to what really can be controlled, and exercising this control in a way that does not so seriously infringe the autonomy of a State as to increase political uneasiness. Accordingly he suggests that the supervision of mines, transport and laboratories should be relinquished because of the consequent large reduction in the need of permanent control in favour of unexpected flying visits by groups of inspectors with permanent authority and guaranteed freedom of movement and entrance to atomic factories, atomic piles, reactor stations, experimental stations and testing grounds. These visits of inspection, moreover, should extend to any places where there is reason for suspecting that a breach of a treaty may occur or be prepared.

Admiral Biörklund believes that a reasonable control organization could be established, and that international negotiations for an agreement to reduce or stop production of cobalt, large hydrogen and atom bombs and also long-range robots should be made. Success in such a restricted task, which in itself may be difficult enough, would assist, he thinks, in the gradual solution of the other more complicated problems when the situation improves. He would model his control organization on that of Western European Union, making use of the foreign military attachés stationed in the respective countries and appointing atomic attachés. In his view, by stopping the production of the large hydrogen and atomic bombs, though existing stocks are kept for the time being and prohibition of their use is conditional, these weapons become a powerful deterrent against aggression, alike for the Western and the Eastern Powers. Moreover, his proposal, by retaining the present balance of power, on which also an agreement can be based, does not require the Western Powers to give up their essential margin of security.

Admiral Biörklund is convinced that, for the sake of humanity, a solution must be found, and he believes that encouraging the development of nuclear energy for peaceful purposes is likely to decrease world tension and enable the Great Powers to satisfy the demands of peace at the expense of those of war.

While Prof. Titterton's survey is rather more comprehensive than that of Admiral Biörklund, he does not attempt to suggest any solution or particular method of control. Until disarmament proposals for weapons of all types, with adequate safeguards of inspection and policing, have been implemented, freedom and survival, he remarks, will depend upon preparedness and strong defence forces. He gives indeed an admirably concise review of Western policy and recent discussions on the control of weapons, and his final two chapters on planning for survival and the steps ahead give a clear indication of the kind of thinking and preparation that are required—thinking of which Mr. Hugh Gaitskell's speech in the House of Commons on July 24 contained more than a hint.

---

* International Atomic Policy During a Decade: an Historical-litical Investigation into the Problem of Atomic Weapons During Period 1945–55. By Admiral Elis Biörklund Translated by ert Read.) Pp. 148. (London: George Allen and Unwin, Ltd., 56.) 15*s*. net.

† Facing the Atomic Future. By Prof. E. W. Titterton. Pp. xi+ +6 plates. (London: Macmillan and Co., Ltd.; New York: Martin's Press, Inc., 1956.) 21*s*. net.

Mr. Gaitskell rightly insisted that whatever new policy we adopt in regard to defence should be hammered out jointly with our friends and allies, and not adopted as each country thinks independently on its own. There is solid truth in his suggestion that the North Atlantic Treaty Organization and the Atlantic Alliance seem unable to decide jointly on the implications of the new situation and that, instead, different countries each say aloud what they expect to do in the circumstances.

The House of Commons debate did not, however, bring out the vital point which Prof. Titterton stresses. It was admitted by Mr. Gaitskell and others that democracies tend to drift apart unless the threat of war is imminent; but the corollary was not faced. If the democracies are to be kept together in the Anglo-American alliance and the North Atlantic Treaty Organization, as Mr. Gaitskell, no less than the Prime Minister, believes they must, more than words are required. A new kind of defence effort is needed in which the public co-operates; and the task of public education that is the first step is only possible if the major political parties co-operate in that task, and cease to make party capital out of even legitimate differences of opinion. Perhaps the biggest problem of defence is that of education—of giving all the people some understanding of the conditions of survival.

Prof. Titterton's book is first and foremost an effort to help in that direction—to help the reader to appreciate those basic facts of the present technological age which every citizen must understand if he or she is to have any influence on the future. That, of course, is also a matter of time, and our second urgent need is accordingly to buy the time in which to achieve the re-orientation of outlook so necessary to a satisfactory solution of the problems of defence. Here Prof. Titterton agrees with Admiral Biörklund as to the need for maintaining world peace through strength, and he considers that with balanced forces at its disposal the West can now meet each type of military threat with an appropriate defence. It is no longer necessary to rely entirely on nuclear bombs, although integration of tactical weapons could greatly strengthen the defence. Thirdly, it is necessary to pursue all possible avenues towards a just settlement of international differences. Mankind can no longer afford the luxury of warfare; fission and fusion weapons have rendered it obsolete as a method of settling international differences. We have still far to go in learning to live together in th changed world; patience, wisdom and human unde standing are still needed, and statesmanship of a hig order. Nor can we count on rapid progress; but peace can be preserved through strength and withou sacrifice of freedom, the chance of establishing a ne order free from fear, and in which full advantage ca be reaped from the possibilities of improved livin offered by nuclear energy to all men, is not t remote.

No less clearly than Admiral Biörklund and Pro Titterton, contributors to the symposium on scien and the affairs of men in the *Bulletin of the Atom Scientists* stress the need for seeing clearly th dangers and tasks of the present. Straight thinkin and a readiness to prepare and adopt radical solutio for the appropriate moment are essential conditio of survival, and the half-century of limited war whi Raymond Aron forecasts could well afford our childr the opportunity to achieve a century of peac Moreover, this clear thinking that is required mu be uninhibited and penetrating, considering n simply the place of science in war but also th implications of science for the relations betwe States in peace as well as in times of tension. Indee the symposium itself offers sufficient evidence of th wide differences in opinion that are likely to be m and the slow rate of progress.

Thus, in the discussion on science and milita strategy, while several contributors agree that nucle and thermonuclear weapons are about to become th mainstay of military planning of the major Power and that their removal from national arsenals is no unlikely, C. W. Sherwin and W. Amster welcome th approaching state of 'mutual deterrence'. The believe that when the two opposing major Powe are demonstrably capable of destroying each other economy and population but demonstrably unab to prevent retaliation, stable peace will result. C the contrary, from the same set of facts, Col. R. Leghorn and D. Inglis reach the radically differe conclusion that the United States and Soviet Russ should arrest the arms race before this ultimate sta of mutual deterrence is achieved. They regard a international agreement to stop further nuclear a thermonuclear tests and to halt the development intercontinental ballistic missiles as our last chanc Stopping at the present level of development thermonuclear weapons and missiles, they believ will preserve a situation which will permit a mo back towards real disarmament when internation relations have improved enough to make extensi international control and inspection feasible. Perha the most convincing argument which Leghorn an Inglis develop for this freezing of nuclear weapons the predicament into which both major Powers cou be put by the acquisition of nuclear weapons b several other smaller Powers. The capacity the two blocks to avoid the outbreak of major war which neither of them wants ma thereby be badly crippled. Furthermore, lil Admiral Biörklund's proposals, those of Legho and Inglis can be enforced without extensi inspection.

It may be that the ideas advanced by Col. Leghorn nd Mr. Inglis have already been judged by official dvisers as technically impossible or coming too late; ut while differences of opinion between technical nd scientific experts are unavoidable, it is not npossible or impracticable to make those differences ntelligible to the layman. Indeed, it is an important art of the task of public education that the reasons r such differences should be explained and made nown to the public. In the radical revision of efence which the British Government is quite rightly ontemplating, it is extremely difficult to make the ght decisions and only too easy to make the wrong hoice. Moreover, such economies as are possible in oncert with our allies cannot do more than enable s to make the best use of our limited resources and void placing an intolerable burden on our economy. hey can do nothing to make for more comfortable ving or lighter taxation, unless we are prepared to bandon all pretence of being a great Power and ccept the incalculable political and diplomatic as ell as economic consequences. There is no escaping therwise the enormous and increasing expense of hermonuclear weapons as the deterrent on which e at present propose to rely.

So long as Britain proposes to share in the strategic eterrent, it cannot escape that cost; and the ientist and technologist as such will have some ontribution to make towards the wise selection and isposition of our resources for that purpose. They n help also in making clear the implications of lternative policies, both for materials and for ientific man-power; and there are scientific and chnical factors which should be taken into account n deciding just what Britain's share in the nuclear eterrent should be. Probably, however, their most nportant contribution will be to the task of public ducation to which Prof. Titterton refers. They can elp to see that misleading statements are duly orrected—that the Chancellor of the Exchequer's uggestion that we might come down to an expenditure of only 5 per cent of our national income on efence is seen as an impossibility. Beyond that, hey can play their part, as the Geneva Conference n the Peaceful Use of Atomic Energy last year has emonstrated, in promoting greater understanding nd unity across national frontiers.

If we can gain time for this task of education, it ay well be one of the most important ways in which ience can contribute to world peace. In an article n "Science as a Force of Unity among Men" contributed to the *Bulletin of the Atomic Scientists* of une, Pierre Auger, arguing that the great task of ur time is to create unity among the peoples of the orld, refers to the great human value of such nternational institutions as the European Council of Nuclear Research. Developments along such lines, e believes, would greatly assist unity and undertanding.

While British scientists should not neglect their opportunities for contributing to international undertanding in such ways, in the field of defence their main responsibility at present is in the task of promoting the formation of a sound public opinion; above all in regard to the implications of nuclear weapons and particularly for our research effort and the distribution of scientific and technical man-power. Even the radical change in strategy and tactics which is involved in any fundamental revision of defence policy in Britain has implications for scientific and technical man-power which need to be considered and explained. If the right decisions are to be reached, it is important that there should be as much informed discussion as possible. If, when the decisions are taken, they are to be firmly executed and faith maintained with our allies, it will be no less important that all that is involved is clearly and fully explained to the public, so that policy enjoys the assured support of an informed and understanding public opinion no matter what political party may be in power.

THE BRITISH FLORA IN RETROSPECT

The History of the British Flora

A Factual Basis for Phytogeography. By Dr. H. Godwin. Pp. viii+384+26 plates. (Cambridge: At the University Press, 1956.) 90*s*. net.

THE foundations of the history of the British flora were well laid when Clement Reid at the end of the nineteenth century published his pioneer work on "The Origin of the British Flora", largely based on seed material which he and his wife collected and identified. But the frequency of such macroscopic specimens as seeds and leaves is poverty compared with the wealth of pollen grains often preserved; it was Von Post who so ably demonstrated this to be a most valuable means of tracing vegetational changes, and his methods were applied in Britain by Woodhead and Erdtman in the middle and late 1920's. From the middle 1930's onwards, Dr. H. Godwin and his associates have exploited this field of study, and the present work is a valuable summary of the rich harvest of their results.

The resistance of pollen grains to decay and their generic and even specific distinguishability render their occurrence of great importance, provided adequate caution is used for guarding against the obvious sources of error. Undoubtedly the most important part of this book is the section devoted to the records of species and genera, which occupy more than half the text and which deal with more than five hundred kinds of plants, fully documented as to the sites from which they have been obtained. Here, for example, the reader can assess the extent of the present evidence for the national status of box, the ancient occurrence of *Lythrum hyssopifolium* or the shrunken distribution of *Polemonium coeruleum*; or again, by reference to *Trapa natans* and *Naias flexilis*, he can envisage some of the evidence for a post-glacial climatic amelioration leading to a climatic optimum in the first half of the Atlantic period.

The text begins with an account of the collection and identification of plant remains, followed by a consideration of Quaternary chronology in which the author provides a tentative scheme of the main vegetational changes from 12,000 B.C. to the present time. Following the plant records already referred to, the author discusses what is termed the pattern of change in the British flora. Here it is apparent, as the author is at pains to emphasize, that, despite the accreted knowledge of the past quarter of a century, there remains a wealth of ignorance and speculative conjecture which only the assiduous collection of further material can remove or justify.

The interplay of climatic, edaphic and historical factors can only be significantly assessed in the light of a far more detailed knowledge than we at present possess of the autecology of individual species and, in particular, of their major physiological responses; never forgetting that, within the same morphological taxon, races of widely differing physiological response may occur, such as the differing photoperiodic response of strains of *Arabidopsis* or alternative reproductive tolerance, as where a species in one climatic complex reproduces by seed and in another by vegetative exuberance.

On the path of his own speciality, we can follow Dr. Godwin with confidence; but when he strays towards the edge his guidance is less reliable. In common with some other phytogeographers, Dr. Godwin appears loth to admit that plant dispersal, although naturally varying in effectiveness with the species and conditions of the habitat, is not infrequently highly successful—perhaps because this introduces an element of uncertainty that is difficult to assess. Thus Dr. Godwin naïvely accepts the increased occurrences of *Himantoglossum* in Britain between the two World Wars as possibly related to climatic conditions and ignores the fact that after the First World War there was a considerable importation of lizard orchids for garden culture. That the plants often seeded freely is a fact, and millions of seeds must have been widely dispersed. The importation is believed to have ceased before the Second World War, and no additional records have in recent years been added. This may be mere coincidence; but on present evidence the facts are at least equivocal. Again, on p. 342 Dr. Godwin states that it can scarcely be doubted that *Bromus secalinus* is a weed, although chess in primitive times, as to-day, was probably cultivated as a crop plant.

But if here and there one feels that judgments have been made on too narrow a consideration of the relevant facts, one cannot doubt that this book is not only a major contribution to this topic, but will also serve as a valuable foundation upon which future work can be based. E. J. SALISBURY

TECHNIQUES AND THEORY OF MOLECULAR BEAMS

Molecular Beams

By Prof. Norman F. Ramsey. (International Series of Monographs on Physics.) Pp. xii+466. (Oxford: Clarendon Press; London: Oxford University Press, 1956.) 75*s*. net.

THERE can have been no more elegant developments of technique in recent years in any field of physics than those that have taken place in the study of beams of neutral atoms and molecules. By combining the techniques of radio-frequency and ultra-high-frequency oscillations with those developed earlier for the production and detection of molecular beams, Rabi and his associates introduced the molecular-beam resonance method which has made possible the measurement of magnetic and electric moments, both of nuclei and of molecules, with an astonishing precision.

In nuclear physics such measurements have been of great significance in the development of current ideas of nuclear structure. In molecular physics they have enabled precise determinations of molecular constants and have contributed to the study of polymerization. But perhaps most important of all has been the contribution of measurements of this kind to the deeper understanding of electron and radiation physics. Precise determinations of atomic magnetic moments established the existence of an anomaly in the magnetic moment of the electron. Using a rather different beam resonance method, Lamb and Rutherford, in their now classical experiment, established the splitting of the $2s_{1/2}$ and $2p_{1/2}$ atomic states of hydrogen and measured it with great accuracy. The remarkable agreement between the calculated values of the anomalous electron magnetic moment and the Lamb–Rutherford shift with the measured values constitutes to-day the most impressive evidence in support of quantum electrodynamical theory and of the essential validity of the mass renormalization methods used in its application to specific calculations.

In this book the techniques of these and many other types of experiment using molecular beams, together with the results obtained and their significance, are described for the first time in a full-length monograph by Prof. N. F. Ramsey, who has himself contributed very much in this field. One has the impression that the author is equally at home whether discussing the finer points of experimental detail or the theoretical bases necessary for the interpretation of the experiments.

Although most of the volume is devoted to the measurement of magnetic and electrical moments, a short early chapter on gas kinetics serves as a reminder that molecular-beam techniques have a considerable importance also in low-energy atomic and molecular physics and in the physics of surfaces. This is followed by a chapter in which the basic expressions for the multipole expansion of the electrostatic and magnetic interactions are set out in a clear and useful form. Then, after a chapter on measurements of the earlier Stern–Gerlach type most of the remainder of the book is devoted to a comprehensive discussion of magnetic and electric molecular-beam resonance methods and their application to the study of nuclear magnetic moments and electric quadrupole moments, the radio-frequency spectroscopy of molecules, the anomaly in the magnetic moment of the electron and the Lamb–Rutherford shift. The interesting possibilities of the development of an atomic-beam clock capable of measuring time-intervals with an accuracy of 1 in 10^{13} and of a molecular microwave amplifier (the 'maser') are discussed briefly. The last two chapters are devoted to the principles used in the design of molecular-beam experiments and to a detailed discussion of the experimental techniques of molecular beam physics.

The large number of carefully chosen figures, the comprehensive tables of data on nuclear moments and molecular constants obtained using molecular-beam methods, and the useful set of appendixes, add greatly to the value of the book, which is likely to remain the standard work in this field for a long time to come. But the book is much more than a description of investigations carried out using molecular-beam methods and a compilation and discussion of the results obtained. By its clear definition of important lines of future development, it should stimulate research in this field, and by its meticulous attention to experimental detail, it should make easier the task of new research workers who may be attracted to such work. E. H. S. BURHOP

DIFFUSION AS A MATHEMATICAL PROBLEM

The Mathematics of Diffusion

By J. Crank. Pp. vi+347. (Oxford: Clarendon Press; London: Oxford University Press, 1956.) 50*s*. net.

THIS book has been written by a mathematician who has worked on diffusion for a number of years and has compiled many of the available solutions of the diffusion equation. It is a book on applied mathematics in which the problems are stated with the minimum of physical description, the main interest being in the method of solution and in tabulating generalized results. The style of presentation is to be recommended to all those who write for non-mathematicians. The discussion is always closely related to the physical problem in hand, particular examples as well as generalized solutions are given, and purely mathematical questions such as uniqueness of solutions, existence theorems and convergence, except where this concerns numerical calculations, are excluded.

The first six chapters, which treat the case of constant diffusion coefficient, form a counterpart to "Conduction of Heat in Solids", by Carslaw and Jaeger (Oxford, 1947). At first glance it would appear that this earlier book covers the subject adequately, it being necessary merely to replace thermal diffusivity by diffusion coefficient. However, many results have been given since 1947, the problems being dictated by the boundary conditions of particular experiments on diffusion rather than heat conduction.

In the present work there are two chapters on the related topics of diffusion with a moving boundary, and absorption with chemical reaction. The latter might well have been expanded; for example, nothing is said about absorption with second-order chemical reaction, a problem of physical importance which presents difficulties of a purely mathematical kind.

The remainder of the book deals mainly with variable diffusion coefficients and with numerical methods. These chapters are rather badly arranged, so that chapters on analytical and numerical solutions with variable diffusion coefficients are separated. There is a useful account of methods of finite differences, in which the brief mention of digital computing machines might have been expanded. A valuable chapter deals with the definition and measurement of diffusion coefficients. Here the author restricts himself to a mathematical discussion, the object being to use the analysis to extract the maximum of information from the experimental data. Such discussion is not out of place in this kind of book, but a little more experimental detail would be helpful, since the analysis available, and the type of experiment which is actually carried out, are interdependent.

The primary value of the book will be to research students beginning the study of diffusion. The earlier chapters will also be useful for advanced undergraduate teaching, while the established research worker will welcome the book as a comprehensive survey of the mathematical literature on diffusion during the past ten years.

It is interesting to note that the author is employed in an industrial laboratory. Until quite recently, theoretical books of this kind were always written by academic workers. Presumably industry is at last realizing the value of advanced mathematics, and it is to be hoped that more theoretical workers in industry will have time to write books of this quality. J. F. DAVIDSON

EARLY CIVILIZATION IN MESOPOTAMIA

From the Tablets of Sumer

Twenty-five Firsts in Man's Recorded History. By Dr. Samuel Noah Kramer. Pp. xxv+293 (40 plates). (Indian Hills, Colorado: Falcon's Wing Press, 1956.) 5 dollars.

FOR more than half a century the Sumerians have held an honoured place in history as the creators of urban civilization in the plains of southern Mesopotamia; but it is only during the past two decades that their highly developed poetical literature has become available in translation, and for this we are indebted first and foremost to the labours of Prof. Samuel Noah Kramer. Others had indeed paved the way by the elucidation of the grammar of the Sumerian language—a language unrelated to any known linguistic group—and by the publication of some of the tablets. However, these tablets, most of which were excavated as long ago as the 1890's, were found broken into many fragments, and at the conclusion of the excavations the fragments were divided between the Museum of the Ancient Orient at Istanbul, the University Museum at Philadelphia, and other collections, before any serious attempt had been made to effect joins. As a result, the fragments copied by scholars over a period of some thirty years were rarely large enough to yield intelligible sense.

The great achievement of Prof. Kramer has been due to his recognition that the most urgent need was the reconstruction of the texts of these compositions. With the support of several American learned societies and institutions, he has devoted all his energies to this task, travelling to Europe and Asia, copying unpublished fragments, and identifying those which belong together. The result has been the rediscovery of a lost literature, which deserves to be made known to a wider public than that reached by the learned journals where the first translations have usually appeared.

This is the main purpose which Prof. Kramer has set himself in this book. However, he has not, as in his earlier work, "Sumerian Mythology" (1944), confined himself to a straightforward presentation of the texts. Rather, he has used the texts to illustrate twenty-five different features of Sumerian civilization, each of which is represented as the earliest known occurrence of a phenomenon familiar in the modern world. These are his "Twenty-five Firsts in Man's Recorded History"—an expression with an oddly academic ring to British ears. Some of these chapter-headings are merely descriptions of actual texts, such as "The First Love-song", "The First Proverbs and Sayings", "The First Tale of Resurrection", "The First Library Catalogue". Others are aspects of Sumerian society deduced from incidental references in one or more texts, such as "The First Bicameral Congress", "The First Experiment in Shade-Tree Gardening", "Man's First Cosmogony and Cosmology". The strange theocratic world-view of the Sumerians is well illustrated by the document translated under the heading "The First Historian". Another text reveals their quaint analysis of their own culture into more than one hundred elements (ranging from institutions like "kingship" to abstractions like "justice" and "terror"), which can be loaded into a boat and carried from one city to another. The remarkably human essay quoted under the title "The First Case of Apple-Polishing" gives a vivid impression of the life of a Sumerian schoolboy; and in the chapter entitled "Man's First Heroic Age", Prof. Kramer draws some far-reaching conclusions about Sumerian origins, which will doubtless not remain unchallenged.

This is a thoughtful and scholarly book, despite the colloquial tone sometimes adopted, particularly in the opening pages. The occasional glimpses of moments in the life of a Sumerologist and his search for 'joins' provide an attractive background to the description of the literature. O. R. GURNEY

EVOLUTION OF MAN

The Fossil Evidence for Human Evolution

An Introduction to the Study of Paleoanthropology. By Prof. Sir W. E. Le Gros Clark. (The Scientist's Library—Biology and Medicine.) Pp. x+181. (Chicago: University of Chicago Press; London: Cambridge University Press, 1955.) 45s. net.

IF Pierre Charron in his "Treatise on Wisdom" was himself wise, the true science and study of man is man. Things, of course, were easier in the sixteenth century when fossil men were not in the laboratory or the study. How much happier we might be to-day if the wisdom of Charron had been coupled with the earlier wisdom of Job, who inquired: "What is Man, that thou shouldest magnify him ?".

Alas, in recent years the study of man has been attempted and magnified by all classes and conditions of men: geologists and palæontologists; anatomists and anthropologists; statisticians and geneticists; blood-group specialists and geochronologists; and adventurers and plain unvarnished liars. Many of the results have added to a confusion that Pope might well have had in mind when he wrote of the "Sole judge of truth, in endless error hurled".

There are, however, ways in which the judges can review the evidence and determine the end of error-making. It may be said that in this slim and elegant volume of a new and enterprising series in "Biology and Medicine", Sir Wilfrid Le Gros Clark has made a brilliant start. This is not easy to do. Man has the palæontological misfortune to be represented fairly generously in the Pleistocene and thus shares in the general regard for antiquity with the taxonomic confusion due to an almost super-abundance of contemporary specimens of the same animal. To all, ancient and modern, a generous amount of anthropomorphization is applied on the lines most familiar to the particular writer.

The answer to the question "What is Man ?" is thus both complex and unsatisfying. It is hard to separate the basic facts from a mass of observation and opinion and from an immense literature. Sir Wilfrid recommends the study of genetics, and rightly so. In "Genetics and the Races of Man" W. C. Boyd in 1950 forecast that more and more attention would become directed to blood-groups; and since he wrote, well over a thousand papers have been published on the subject—a sobering thought on the evolutionary picture. The strongest possible support must be given to Sir Wilfrid's plea that the student of human evolution should have a much closer acquaintance with the facts of functional anatomy. Without this and the assurance it gives for critical appreciation of structural analysis, all the highly important new work on the dating of the Pleistocene will be much reduced in value and the evolutionary pathways indubitably obscured.

The accumulation and recognition of a total morphological pattern is not simplified either when, through lack of anatomical knowledge, the desire to create new genera or species on every fragment of hominid bone persists. The current value of human remains is sometimes to be assessed by the value the observer places upon his observation rather than upon the intrinsic characters of the specimen.

It is of paramount importance that Sir Wilfrid here approaches the subject from the point of view of the scientific palæontologist and examines each piece of evidence as if it belonged to some anima other than man. He pays primary attention to the morphological and phylogenetic problems in taxonomy in relation to hominid evolution. This leads to a sound taxonomic system based on comparative anatomy, and placed on a background of geologica time, that enables the distinction of hominid and pongid radiations to be made.

In the major portion of the book he follows the story of man's evolution in the logical way—from the known to the lesser known, the unknown and the postulated. In this route he recognizes taxonomic categories for *Homo sapiens*, *Homo neanderthalensis* *Pithecanthropus* and *Australopithecus*.

Each of these sections ends with a diagnosis of the genus concerned and a discussion of its relationship with the other genera. The final chapter is on the origin of the Hominidae.

So far, the author says, no undoubted hominids have been found of an antiquity clearly older than the Early Pleistocene, and so far no fashioned implements have been proved of any greater antiquity. The relics of Pliocene hominids have yet to be discovered, though there is no doubt that such hominids existed.

It is thus all the more important to be able to be precise about the characters that these may have possessed and which will serve to distinguish them from the ten (at least) genera so far described o anthropoid apes of Pliocene and Miocene age.

The text is well illustrated by line-drawings, and there is a long and useful list of references. As a whole, the book will be of great interest to the anthropologist and quite invaluable to the student Not the least of its appeal to vertebrate palæontologists is the fresh draught of common sense tha the author lets in on the nomenclatural fog. Thi is a wise and valuable addition to the library of th palæontologist and physical anthropologist, and i can also be read by the layman.

W. E. SWINTON

Arabic Astronomical and Astrological Sciences in Latin Translation

A Critical Bibliography. By Francis J. Carmody. Pp. vi+193. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1956.) 21*s*. net.

THE purpose of this bibliography is to present in a co-ordinated form all known translations into Latin of Arabic works on astronomy. Most of the known Arabic works were translated into Latin during the medieval and renaissance periods by scholars who were specialists. In these translations they were able to exert a marked influence on European thought. The translations are of use to a far greater number of scholars than the Arabic originals would be; moreover, many of the original Arabic texts have not survived.

This bibliography has been prepared with great care by co-ordinating and corroborating the various editions and manuscripts. Several hundred manuscript texts have been examined at first hand. Works on astrology have been included as many of them contain technical information on such matters, for example, as planetary theories and improvements in astronomical constants. Mathematical works have also been included where they touch on the borderline of astronomy and deal with such matters as optics or the astrolabe.

A chronological arrangement of authors has been followed. Some brief notes about each author are given, followed by lists of editions and of manuscripts and some idea of the reliability of each. The contents of each work are described and an estimate of its significance is given. The locations of the several manuscript copies believed to be suitable for research are listed.

The preparation of this bibliography has evidently entailed an immense amount of research. It will provide an invaluable reference source for all students of Arabic astronomy. H. SPENCER JONES

Unione Internazionale di Chimica Pura e Applicata

Simposio Internazionale di Chimica Macromolecolare, Milano–Torino, 26 Settembre–2 Ottobre, 1954. (Supplemento a *La Ricerca Scientifica*, Anno 25.) Pp. xix+954. (Roma: Consiglio Nazionale delle Ricerche; New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1955.) 12,000 lire; 19.20 dollars.

THIS volume comprises some 106 papers contributed to the International Symposium on Macromolecular Chemistry, which was held under the auspices of the International Union of Pure and Applied Chemistry, in Milan and Turin, during September 1954.

The editors and printers have carried out their difficult and laborious task well, and the result is a substantial volume which gives an excellent permanent record, not only of the papers contributed, but also of the discussion remarks. The majority of papers are in English or French; but in all cases a lengthy résumé is given in Italian, French and German; so that the volume as a whole is a very valuable contribution to the international literature on this subject; it is clearly a necessity for the libraries of all institutions and laboratories concerned with macromolecular chemistry. It is only unfortunate, but quite understandable, that so much time should have elapsed between the conference and the volume. The subjects of the discussion were: (1) building reactions of macromolecules; (2) transformation reactions of macromolecules; (3) block polymers and graft polymers, preparation and properties; (4) cellulose and derivatives; (5) molecular weight determination and distribution; (6) branched polymers; (7) fibre-forming high polymers; (8) crystallization and transitions; (9) proteins; (10) general properties of polymers. J. A. V. BUTLER

Welt, Ich und Zeit

Nach unveröffentlichen Manuskripten Edmund Husserls. Von Gerd Brand. Pp. xviii+1012. (Den Haag: Martinus Nijhoff; London: B. T. Batsford, Ltd., 1955.) 9.50 florins.

THIS scholarly volume deals with the unpublished Husserl manuscripts. They represent the state of affairs existing at the end of the philosopher's life, and comprise his heroic attempts (never perhaps, in his estimation, wholly successful) to set phenomenology fairly and squarely upon an irreproachable methodological basis. Thus is explained the division of the work into two parts. In the first, no more than a general introduction to the subject is achieved, whereas in the second Husserl brings to bear his constitutive analysis with that particular brand of rigour which impelled him to regard phenomenology as a portion of a living science.

So, his meditations upon the return to experience occupy about one-third of the book, and his concept of temporality as fundamental for such experience the remaining two-thirds. The contrast is between occasional truths—with which we have to be satisfied in everyday life—and final validity. Observed historically, this means that the choice for Europe (as Husserl saw it) is between decay into barbarism or the rebirth of a spirit of philosophy in which objectivity would play a major part. It seems safe to deduce from these pages that something less violent than the "Enlightenment" of French savants is envisaged, but at the same time a system capable of eliminating the crudities of a merely pragmatic theory of knowledge. F. I. G. RAWLINS

The Theory of Differential Equations

By Dr. J. C. Burkill. (University Mathematical Texts.) Pp. ix+102. (Edinburgh and London: Oliver and Boyd, Ltd., 1956.) 8*s*. 6*d*. net.

INCE'S volume in the "University Mathematical Texts" gave an account of standard forms of explicit solution of ordinary differential equations. Dr. Burkill's companion volume takes this material as known, and proceeds to discuss conditions under which the existence of a solution may be proved, and those properties of the solution which may be deduced from the nature of the differential equation. The theory of the linear equation is concisely but thoroughly developed, an introduction to the Sturm–Liouville theory is given, solutions by means of infinite series and by contour integrals are carefully discussed. Chapters on the Legendre and Bessel functions serve as illustrations of general methods, and there is a brief introduction to asymptotic series. To cover this ground in a hundred small pages demands expository skill of no mean order, and it is a measure of the author's mastery to find a lucid account, easily intelligible to any good honours student, in so small a compass. Both as a text in itself, and as an introduction to more comprehensive treatises in this field, this book is a worthy member of the excellent series to which it belongs.

T. A. A. BROADBENT

ZOOLOGICAL RESEARCH AND ANIMAL LEARNING

ON the first day of the recent meeting of the British Association at Sheffield, the presidential address by Dr. W. H. Thorpe to Section D (Zoology) (see *Nature*, September 1, p. 473) was followed by a series of papers on "The Contribution of Zoological Research to Theories of Animal Learning".

Dr. Peggy E. Ellis (Hope Department of Entomology, Oxford) opened with an account of some experimental work on gregariousness in the desert locust (*Schistocerca gregaria*). Locusts reared in the laboratory in company with other individuals started to form groups some hours after hatching. When ten such individuals were tested under standard conditions in a ring-like cage, 70–80 per cent formed groups by the end of the first day, and the proportion remained more or less constant on the following days. Locusts reared in isolation and afterwards placed in crowded conditions, however, at first tried to escape from aggregations, and became gregarious only after several hours. When such individuals were tested in the ring-like cage, at first only 45–55 per cent formed groups, though the proportion rose to 70–80 per cent during the first day. Once the locusts had learned to aggregate, the behaviour seemed to be fixed. Thus insects kept under crowded conditions for three days, and then isolated for several days, did not lose their gregarious tendency.

From such experiments it seems that positive gregariousness depends on a learning process which resembles 'imprinting' in being rapid, irreversible and in involving a learning of 'supra-individual' characters. It differs from imprinting in that there is no sensitive period—individuals reared in isolation can learn to become gregarious at any age. Dr. Ellis related her experiments to the behaviour of hoppers in the field and her lecture was illustrated by a colour film taken in Ethiopia.

Dr. S. A. Barnett (Department of Zoology, Glasgow) then presented a paper on "Animal Motility and Learning". Early scientific work on animal movement was concerned primarily with the control of orientation and directed movement, the approach being narrowly mechanistic. Later, the importance and role of appetitive behaviour were appreciated, and investigators were concerned with the initiation as well as the orientation of the movement. Dr. Barnett used the term 'appetitive behaviour' only for behaviour which is (*a*) specifically motivated and (*b*) related to a consummatory act, and pointed out that some variable movement is not appetitive in this sense. Thus 'exploratory behaviour' is widespread among animals but does not lead to any specific act. Appetitive and exploratory behaviour are important in that they provide opportunity for learning—exploratory behaviour, in particular, makes possible topographical learning. Such learning is independent of the satisfaction of a particular need—a fact surprising to the learning theorist accustomed to manipulate motivation in experiments on learning, but not to the zoologist, who thinks in terms of survival value. In its independence of specific needs and acts, exploratory behaviour resembles play; such behaviour is of course of particular importance in the primates and in man.

The first paper in the afternoon, by Dr. R. A. Hinde (Ornithological Field Station, Department of Zoology, Cambridge) was concerned with "The Significance of Imprinting"—'imprinting' being used in its original sense to refer to the learning of the characteristics of their parents by young birds, and especially to the learning occurring when young nidifugous birds follow their parents. Among the characteristics of imprinting and the following-response discussed were:

(*a*) The diversity of objects which can elicit following. This can be understood functionally: responsiveness limited to one or a few stimulus patterns would be too selective, for the juveniles have not yet acquired a sense of constancy of size and shape and might fail to follow the parent when the latter was seen in varying postures and from varying angles.

(*b*) The ambivalence of the young, which tend to flee from their parents as well as to follow. This is a consequence of the selective advantage to adults of caring only for their own offspring and of driving off others.

(*c*) Irreversibility, rapidity and 'the sensitive period'. By virtue of such characteristics Lorenz believed imprinting to be a special form of learning. These characteristics are, however, by no means peculiar to imprinting, and can be found to a comparable degree in other contexts. Furthermore, all are covered by William James's laws of instincts.

(*d*) Imprinting and the parent-offspring relation. For a full understanding, imprinting must be considered in relation to all the behaviour patterns operating between parent and young: it plays an essential part in building up the parent-offspring relationship.

Since the characteristics of imprinting in birds can be understood functionally, learning with similar characteristics can be expected in other contexts with similar functional requirements. Thus the relationship between human mother and baby is built up in a similar way and shows many characteristics in common with the analogous relationship in birds, though the underlying mechanisms are presumably different.

A paper by Dr. I. M. L. Hunter (Department of Psychology, Edinburgh) entitled "'Trial and error' versus Insight" followed. Much of the problem-solving behaviour of animals seems to be 'almost human', and it seems reasonable to suppose that the animal 'understands' the situation. Such a supposition may, however, be wrong, for the animal has had a long learning history during which complex performances may have been developed by a process of trial-and-error learning which in no sense indicates the presence of thinking. In other cases the apparently intelligent behaviour of an animal may even turn out to be devoid of any learning at all: thus some of the strikingly purposeful behaviour of insects has been found to be instinctive, depending on a complex behaviour pattern which is, as it were, built into the organism.

The question whether animals think is thus more difficult to answer than it might appear. We need to know whether animals, whose past history is known in detail, can reorganize their past and present experiences to produce an anticipation of truly novel relationships within the problem situation. Only if this is so is it justifiable to speak of 'thinking' in animals. However, within the past ten years this has been actually demonstrated. In chimpanzees, kept under continuous observation from birth, familiar material may suddenly and adroitly be used in a genuinely novel way as, for example, when a T-shaped stick is used to rake in food which lies out of manual reach beyond the bars of the cage. In white rats, certain types of maze experiment—the so-called reasoning and latent-learning experiments—have shown that these animals can make inferences about the spatial characteristics of certain situations, since they can run deftly from one place to another by paths which they have never before traversed. These and other findings lead to the conclusion that thinking exists not only in humans but also in animals, at least within the mammalian range.

Dr. Hunter suggested that the importance of such experiments not only demonstrates the existence of animal thinking but also contributes to the understanding of human thought processes. They have shown, for example, that thinking occurs only when the animal has had certain appropriate experiences in the past, experiences which contribute to thinking by furnishing, as it were, the raw material out of which a new response pattern can be formed. The experiences of early life seem to be especially important in this respect. Because it is easier to control the exact conditions under which animals can be reared (whether, for example, their visual environment is rich or lacking in detail), experiments with animals are particularly suited to yield information on the effect which early perceptual learning has on the emergence of thinking. In this way, animal experiments will supplement the considerable body of work which is currently being done on the nature and development of human thinking, and will provide answers to questions which could not be feasibly tackled at the human level.

Dr. A. J. Watson (Department of Experimental Psychology, Cambridge) discussed " 'Stimulus-response' Theories of Animal Behaviour in the Light of Work on Instinctive Behaviour". He directed attention to three ways in which work on instinctive behaviour could lead to modification in theories of learning as devised by psychologists.

(*a*) Theories of learning are really theories of 'behaviour'—they attempt to predict what an animal will do in a certain range of circumstances. Furthermore, current learning theories are all in a sense stimulus-response theories; that is, given one set of stimulus conditions, and another of response conditions, an attempt is made to unite the two so that the second can be inferred from the first, but nothing is postulated about the actual mechanisms which intervene. Just because the initiating conditions, the final state and the intervening mechanisms are so complex, such attempts at prediction are almost bound to fail. Another type of approach is therefore necessary.

This is provided by instinct theories (for example, McDougall, Tinbergen) which permit distinctions between different 'kinds of responses' in different situations; for example, between appetitive and consummatory behaviour. Such distinctions cannot be accommodated within, for example, the Hullian framework, and permit an analysis of the problem so that it can be studied piecemeal.

(*b*) Instinct theories have emphasized the goal-seeking and directive properties of behaviour, which enter rather as an afterthought into theories of learning. This is related to the concepts of motivation used; in ethological theories the 'drive' selects the stimuli for which the animal searches in its appetitive behaviour, while in learning theory the drive serves only to provide a perpetual internal stimulus which may become linked to responses in the same way as an external cue. Further, the retroactive effect of drive reduction in learning theory is without parallel in instinct theories. The instinct-type theory, involving a 'goal-seeking' system, is superior to a stimulus-response system both because of its simplicity and because it can deal more readily with variable behaviour leading to a constant end. The retroactive effect of drive reduction is an unnecessary postulate, for goal-seeking machines can be made to learn what cues to search for without invoking any such principle.

(*c*) Dr. Watson suggested that instinct and learning theories differ in the nature of the goals which they postulate. While instinct theories have tended to emphasize the importance of acts as goals, psychologists have laid more stress on the perception of stimuli. The evidence is in favour of the latter view, and on this issue, therefore, ethologists seem to be farther from the truth than students of the theory of learning.

Thus ethological studies suggest that the student of the theory of learning should attempt to build a theory of a different logical type—with room for different 'kinds' of behaviour—and that he should modify his treatment of motivation. Ethologists, on the other hand, could usefully study the treatment of consummatory situations by learning theorists.

Finally, Mr. R. L. Reid (Department of Psychology, Aberdeen) spoke on "Avoiding Theory", expressing the view that the study of behaviour might progress more rapidly with fewer theories. Among the types of theory which could, in his view, profitably be discarded are:

(*a*) Escapist theories which attempt to explain a phenomenon away. Thus when a worm learns to turn into that arm of a T-maze in which it is shocked, its behaviour can be explained away by saying that 'worms like electroshock', or by supposing the synapses to be directly affected by shock. The first is mentalistic, the latter a physiological fairy tale, and both are unverifiable: they merely translate statements about behaviour into a different language.

(*b*) Behavioural cosmologies. These are superordinate theories which usually reflect the theorist's values and metaphysical assumptions, but are irrelevant to the practical aim of predicting behaviour. Arguments about holism and analysis or the purposeful nature of behaviour may obscure agreement about facts.

(*c*) Formal theorizing. This results from the use of hypothetico-deductive schemes (for example, Hull) and theoretical models (for example, Estes, Bush and Mosteller). These are unlikely to be fruitful in the study of broad areas of behaviour because of the complexity of the problems involved. Although they may be suitable for exploiting limited areas where the facts are already known, the urgent need —while the gaps in our knowledge are still so great—is for factual survey work. Such formal approaches are inevitably constrictive: although there is room for formal theorizing, the less pretentious inductive approach must not be neglected.

(*d*) Physiologizing. In thinking about complex behaviour it is sometimes disadvantageous even to consider possible mechanisms. Thus the concepts of 'set' and 'attention' were disposed of in the early stages of behaviourism largely because they did not fit in with the picture of the nervous system then held. They have now been restored on the grounds that they are physiologically respectable. Behaviour is as real and as regular as the physiological events underlying it, and reduction from the one realm of discourse to the other is unnecessary.

Mr. Reid concluded by hoping that zoological research will continue to provide empirical studies of learning in a wide variety of animals, and to examine the effects of hitherto neglected variables, rather than indulge in speculative theorizing.

In his concluding remarks, Dr. Thorpe directed the attention of those present to the growth of liaison between psychologists and zoologists studying behaviour. Five years previously they would barely have understood each other's problems, whereas now each has a broad knowledge of the other's work and they are aiming at similar goals. R. A. HINDE

THE PHYSICAL PROPERTIES OF METALS

ALTHOUGH the British Association has no section dealing specifically with metallurgy, it was to be expected that the recent meeting in Sheffield should give prominence to the subject. Thus the morning session of Section A (Physics) on September 3 was devoted to physical metallurgy, and Sir George Thomson, president of the Section, presided. The first paper, "The Physical Approach to Metallurgy", was presented by Prof. A. G. Quarrell (Sheffield) and served as an introductory lecture to the morning's proceedings. It emphasized the complexity of the technology of metals to-day and described how physics has provided not only the techniques for studying metals but also the necessary mental approach to the ultimate nature of metals which is leading to an understanding of their strength and behaviour.

Metallurgy as a science dates from the application of the microscope by Sorby to metal specimens at Sheffield in 1863, and a unique series of ferrous metallographic specimens laboriously prepared by Sorby in 1864 was on view at the meeting. Fortunately, these have been preserved by a cover-glass cemented on each prepared surface, and many may still be examined at high magnification. Sorby realized that the structure visible in polished and etched specimens is characteristic of the metal and the way it has been produced, and some time later it was shown that the appearance is also related to the mechanical properties of the metal.

The maximum magnification with the optical microscope is about × 2,000, but about fifteen years ago the development of the electron microscope led to an increase in the useful magnification up to × 100,000. Unfortunately, direct observation of the metal surface is normally impracticable, and a replica which is transparent to electrons must be examined. The initial unreliability of replica techniques prevented the general acceptance by metallurgists of electron microscopy, but the use of vacuum-deposited carbon replicas during the past two years has completely revolutionized the situation, and the electron microscope is now a most powerful metallurgical tool.

The early optical microscopic examination of metals was soon supplemented by thermal and dilatometric studies, enabling the composition limits of the various metallic phase fields to be determined and constitution diagrams to be constructed. The understanding of the alloy formation, however, had to wait for the technique of X-ray diffraction and for the concept of a metal as an assembly of charged ions surrounded a cloud of the conducting electrons. Hume-Rothery then showed in 1926 that the limiting solubility in monovalent metals such as copper and gold depends on the relative atomic diameters of the metals concerned, and that the structure of the intermediate alloy phases depends on the ratio of valency electrons to atoms in the alloy. These rules unfortunately fail to explain the alloying behaviour of the more complex alloys which are important in modern technology, and the approach to these alloys is still largely empirical.

The appreciation of the crystalline structure of metals has also made possible the study of the factors influencing the strength of metals. However, the theoretical strength of metals calculated from their atomic properties is 100–1,000 times greater than the measured stress required to produce permanent plastic deformation. This weakness is due to imperfections in the lattice, known as dislocations, and since the 'edge' dislocation was introduced in 1934 a complex theory of dislocations and their behaviour in crystal lattices has been developed. It has been calculated that the stress necessary to move a dislocation, if the interactions between the dislocation and the stress fields due to alloying atoms and precipitates are taken into account, is similar to the stress required to initiate slip in practice.

The dislocation theory of plasticity has been developed by theoretical physicists such as Mott and physical metallurgists such as Cottrell, and while strain-hardening, yield-points and crystal growth have been explained satisfactorily, only a beginning has been made towards the understanding of creep, fatigue and brittle fracture.

Creep is an example of a phenomenon of interest to both physicist and metallurgist; it was studied by Andrade in 1910 as a purely scientific phenomenon, but in 1920 Dickinson, in Sheffield, appreciated the importance of creep in steels at high temperatures and carried out the first long-time creep tests. These showed that at high temperatures much lower stresses would cause stretching and failure in the long-time creep test than in the short-time tensile test. The importance of creep in modern engineering has grown enormously in recent years with the trends towards high operating temperatures and pressures, and a large proportion of our metallurgical man-power is concerned with the development of new creep-resistant alloys which, for example, would be expected to last for many years at 570° C. in a modern power station.

Although complex metallurgical problems such as the mechanism of creep and its relationship to structure have not been solved completely by the physical approach, and resort must be made to semi-empirical methods, the major contribution of physics to metallurgy has been to give metallurgists a new mental attitude. Metallurgists are no longer satisfied with *ad hoc* solutions of immediate problems and have become increasingly anxious to provide fundamental explanations of important phenomena.

This truly scientific approach will undoubtedly result in rapid advance of the science of metallurgy.

"The Microstructure of Metals and Alloys" was the subject of a paper by Prof. C. S. Smith (Chicago). At the time of Sorby, the grains visible in metallographic micro-sections were not recognized as single crystals, because the single crystals of minerals in Nature were always expected to be regular polyhedra. However, it is now realized that the requirements of space filling prevent metal crystals in a polycrystalline aggregate from exhibiting regular crystallographic faces, and the geometry of the grains is governed by the condition that the interfaces contribute minimum energy to the system.

The interfaces themselves are of considerable interest as the interface atoms belong to both adjacent crystals. They have abnormal co-ordination with their neighbours, and abnormal spacing from them, making the interface a high-energy region which may be regarded as constituting a thin layer of liquid between the grains. A micro-section is essentially a random two-dimensional section through an aggregate of grains, and in a section the relationship between the number of polygons (P), the number of edges (E) and the number of corners (C) is given by the two-dimensional form of Euler's Law:

$$P-E+C=1$$

This shows that a grain can have any number of sides greater than two, but that hexagonal polygons are the most common.

Although polygons of other than six sides are possible and do occur, the condition of minimum energy in the boundaries invariably results in the grain boundaries meeting in threes at angles of 120°, and such junctions can only be accommodated by curved boundaries. In three dimensions the grain edges meet each other in fours at angles of 109½° to each other at each junction. These four crystal junctions are the only constant unit of structure and may be connected in innumerable ways. A three-dimensional array is thus made up of irregular grains each with approximately fourteen faces, and each face having an average of 5$\frac{1}{7}$ faces.

The arrangement of the grains in beta brass can be revealed by fracturing in the hot-short range and is analogous to that of the bubbles in a soap froth or the cells in human fat, as they are all controlled by the requirement that the interface energy, and hence the area, must tend to a minimum.

Such grains show curved faces, and if a metal is heated to the temperature at which diffusion can occur, the boundaries move towards their centres of curvature and the smaller, convex, cells disappear while their concave neighbours grow. The final minimum-energy state would consist of a single crystal.

In two-phase alloys the same relations between the grains apply, but the dihedral angle between the grains usually differs from 120° as the interfacial tensions are usually different. This angle is often zero for a liquid between two crystals which breaks all coherence, as in brass in contact with mercury or molten solder. In solid two-phase alloys the angle is often between 90° and 100°, showing that the chemically different interface is of lower energy than that between the two crystals of the same phase.

In this treatment it has been assumed that the energy of the interface is independent of the orientation between the grains forming the grain boundary; but this generally correct assumption breaks down at certain critical orientations. Thus the twins and plate-like precipitates which are due to a nucleation and growth processes, orientate themselves to give the lowest possible energy, and this outweighs the spatial improbability of such relationships. The majority of precipitates within the grains of heat-treated structures are of this type, exhibiting an orientated, polyhedral habit.

These general principles of space filling by polyhedra to give the minimum area, and hence minimum energy, of the interface, apply not only to metals but also to other microcrystalline materials such as ceramics and rocks, and all structures and transformations can be classified in terms of the structure of the boundary and the kind of adjustments in composition and position which occur as the boundary moves.

Dr. N. J. Petch (Leeds) spoke next on "Brittle Fracture", a subject he has made peculiarly his own. A fracture is defined as brittle if it is associated purely with elastic deformation and the fractured metal thus shows no evidence of deformation.

The difference between a brittle and a ductile crack is in its method of propagation. In the former case the applied stress required to spread the crack decreases as the crack grows; hence the maximum stress is required initially and catastrophic propagation occurs once the crack is initiated. If the crack is ductile, some energy is expanded in deforming the ends of the crack, and continued straining is necessary to spread the crack.

Although a mild steel may be quite ductile in a tensile test, it may behave in a brittle manner when incorporated into a structure. This difference has become more obvious with the use of all-welded structures, in which a crack, once started, can often travel a very large distance before being arrested by a physical discontinuity. More than one-fifth of the 5,000 ships built under the American emergency shipbuilding programme during the Second World War suffered serious cracking within three years, and eleven had broken completely in half by 1951. Other serious fractures have occurred in bridges and oil-storage tanks, and outstanding fractures a mile long have been reported in 30-in. diameter natural gas pipe-lines in the United States. These fractures travel with speeds approaching the speed of sound in the metal and a mile-long fracture would thus occur in about one second.

It is found that brittle materials exhibit a strength which is approximately one-thousandth of that calculated for a perfect solid, and Griffith laid the foundation of our present understanding of brittle fracture by showing that in glass and silica this weakness is due to minute cracks acting as stress concentrators. The current ideas of metallic fracture regard these stress concentrators as dislocation pile-ups on slip planes blocked by grain boundaries, and the stress concentration of × 1,000 necessary to account for the difference between the observed and theoretical strengths would require a thousand piled-up dislocations. which is not unreasonable. The difference between brittle and ductile materials is in the behaviour at the pile-up; in ductile metals crack formation is accompanied by plastic deformation, so that energy is lost in initiating the new dislocation movements, and the resulting crack is too small to propagate itself; many small cracks are thus formed which eventually join up and cause failure. In brittle failure, the propagation is elastic and no plastic deformation occurs, so that all the energy of the dislocation pile-up goes into the production of the crack and the initial crack is sufficiently long for spontaneous propagation.

Metals are most prone to brittle failure if movement of the dislocations, that is, plastic deformation, is difficult; for example, mild steel shows more brittleness than, say, copper because the dislocations become locked by carbon atoms, and this effect becomes more pronounced the lower the temperature.

The dislocation model also explains why brittle cracking is often observed in structures when a test piece of the same steel is ductile. Notches in the structure cause stress concentrations at their roots at which the rate of strain is high and dislocation movements are not rapid enough to avoid brittle fracture.

In general, the physical explanation of brittle fracture in polycrystalline metals is satisfactory, but the mechanism of the fracture in single crystals is still obscure.

In his paper on "The Metallurgy of Nuclear Energy", Mr. L. Rotherham (United Kingdom Atomic Energy Authority) outlined the metallurgical problems in the design of nuclear reactors. A thermal reactor consists essentially of a lattice of uranium rods surrounded by a moderator, usually of graphite. When a chain reaction is allowed to take place in the uranium, heat is generated and the pile must be continuously cooled. This is accomplished in the Harwell and Windscale piles by the use of air as a coolant and at the Calder Hall power station by carbon dioxide under pressure.

The problems encountered may be divided into those of a conventional nature which might be encountered in general chemical engineering, and those in which radiation effects are important. A typical conventional problem was the construction of the steel pressure vessels at Calder Hall, which are 40 ft. in diameter and 60 ft. long, containing carbon dioxide under pressure to increase its efficiency as a coolant. These vessels were fabricated by welding two-inch thick steel, and to avoid the brittle fracture dangers discussed by Dr. Petch, they were made of special steels.

The fuel elements consist of uranium rods protected by aluminium or magnesium 'cans' to prevent attack by the coolant. Unfortunately, uranium has low crystal symmetry with three markedly differing coefficients of thermal expansion along the three orthogonal crystal axes, and on heating and cooling considerable thermal distortion can occur in polycrystalline material. The effect of irradiation is similar, and considerable dimensional changes can also occur due to the internal strains produced by the fission products, which occupy more space than the parent uranium atoms. This effect is aggravated if atoms of rare gas are produced, which afterwards diffuse into voids and set up a considerable pressure. At 200° C. a single crystal of uranium would approximately double its length after the fission of one in a thousand uranium atoms. Irradiation of cast polycrystalline material produces an orange-peel surface wrinkling, while rolled material may increase its length and decrease its width, or vice versa, according to the rolling temperature. A further complication arises from the phase change in uranium at 650° C., as repeated heating and cooling through this transformation leads to severe distortion and surface roughening. The metallurgists' problem is to minimize these effects by heat-treatment to produce smaller grain-size, to avoid any preferred orientation due to fabrication and to study the effects of alloying which might stiffen the rods and thus help to resist the effects of internal pressure.

It is also possible to prevent distortion of the fuel elements by enclosing them in a rigid can. The Harwell and Windscale reactors employ aluminium cans; but as the fuel elements are discharged for plutonium extraction after relatively short periods in the pile, the distortion problems are not severe. In the Calder Hall reactors, power and not plutonium production is the main objective, and to withstand the severe distortion and growth consequent on a high burn-up of uranium, magnesium was chosen for the canning material. Magnesium has a higher creep strength than aluminium, and as it has a lower neutron absorption cross-section, a thicker and more rigid sheet can be used for the can.

In the future, the higher temperatures of fast reactors as envisaged at Dounreay will preclude the use of aluminium and magnesium as canning materials, and new metals will have to be employed. The choice is limited by the requirement that the metal must have a low neutron absorption, and use must be made of the rarer metals beryllium, zirconium, niobium, vanadium, tungsten and molybdenum. Of these metals niobium perhaps offers the most advantages, in that it is the most resistant to attack by uranium and liquid sodium, it has good high-temperature strength and it is extremely ductile and therefore readily fabricated into cans.

Up to the present, the extraction and properties of the rarer metals have been explored, and future developments will lie in the direction of enhancing the usefulness of these metals by alloying.

R. G. WARD

THE ELECTRICAL CONDUCTIVITY OF THE HEAD-WATERS OF THE WHITE NILE

By R. S. A. BEAUCHAMP

East African Fisheries Research Organization, Jinja, Uganda

FOR many years records have been kept of the levels of the lakes that form the head waters of the White Nile, and estimates have been made of the amount of water discharged from these lakes. Yet some uncertainty still exists regarding the relative contributions made by these various sources. This is not surprising when one considers the extent and complexity of this lake and river system, and the fact that the whole area is subject to high and irregular rates of evaporation and precipitation. The purpose of this article is to indicate the value of keeping, in addition to records of lake-levels and rates of discharge, records of the electrical conductivity of the water at particular points in the system. The electrical conductivities of these lakes and rivers cover a wide range of values. A study of hese values provides information on the amounts of vater derived from different sources.

Lakes Victoria and Kyoga form a major portion f the head waters of the White Nile ; the outlets of hese two lakes give rise to the Victoria Nile, which ischarges into the northern end of Lake Albert close o its outlet. The rest of this system is composed of series of three lakes : Lakes George, Edward and lbert. Values for the electrical conductivity of the vater contained in these five lakes remain nearly onstant and are as follows :

Lake Victoria	100	Lake George	160
Lake Kyoga	330	Lake Edward	910
Lake Albert	720		

The more important rivers in this system are the ictoria Nile, already referred to, the Semliki and he Albert Nile. The Semliki flows from Lake Edward o Lake Albert. The Albert Nile is the outflow from ake Albert.

The electrical conductivity of the Victoria Nile, easured just below the Murchison Falls at Fajao, emains at a nearly constant value of 110 units.

The electrical conductivity of the Semliki varies long its course and at different times of year. The ganda Hydrological Survey Department has on is river three recording stations. The first of these ations is at Ishango, close to the outlet from Lake dward; the second is at Ngamba, about half-way own the river; and the third is at Bweramule, irty miles from Lake Albert. My thanks are due the Hydrological Survey Department for supplying mples of water from these three stations.

At Ishango the electrical conductivity of the water almost constant at 910 units, being undiluted Lake dward water. At Ngamba values recorded range etween 780 and 885 units; at Bweramule they nge between 360 and 800 units (see Fig. 1). The riations in conductivity of the water at Ngamba d at Bweramule indicate that the Semliki at times ceives considerable quantities of water of low nductivity on its way to Lake Albert.

The conductivity of the Albert Nile measured at kwach ranges between values of 160 and 355 (see ble 1). My thanks are due to the Commander-in-arge, Lake Albert, East African Railways and arbours, Butiaba, for samples of water from kwach and from mid-lake. It can be seen that nductivity values at Pakwach are entirely different om the value of 720 recorded for Lake Albert. The bert Nile cannot therefore be considered simply as e outlet of Lake Albert.

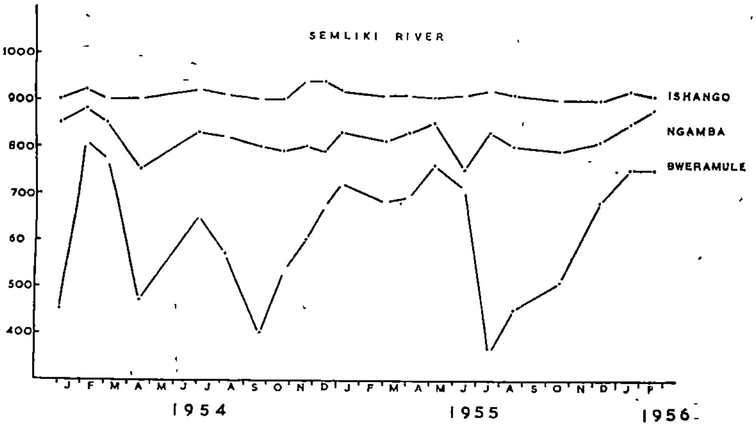

Fig. 1. Values for the electrical conductivity of the Semliki River at three stations

Table 1. VALUES FOR THE ELECTRICAL CONDUCTIVITY OF THE ALBERT NILE AND ESTIMATES OF THE PERCENTAGE OF LAKE ALBERT WATER CONTAINED IN THIS RIVER

Date	Electrical Conductivity Pakwach	Per cent Lake Albert water at Pakwach	Date	Electrical Conductivity Pakwach	Per cent Lake Albert water at Pakwach
25.3.54	310	33	26.8.54	210	16

12.8.54	280	28	20.2.55	250	23
19.8.54	205	15	3.3.55	280	28

Samples of water collected along a course running south from Fajao out into Lake Albert show that very little water from the Victoria Nile finds its way into Lake Albert. At a point approximately ten miles south of the Victoria Nile Delta, the water has a conductivity value of 720. It seems, therefore, that nearly all the water in the Victoria Nile travels almost directly into the Albert Nile.

Summarizing the information given above and the data contained in Fig. 1 and in Table 1, it can be said that the waters of the five lakes, which form the head waters of the White Nile, have electrical conductivities which remain constant at values characteristic for each lake, and that the water in the Victoria Nile also has a characteristic and almost constant electrical conductivity. On the other hand, the water in the lower reaches of the Semliki and in the Albert Nile show widely fluctuating values.

The electrical conductivity of natural waters is directly related to the concentration of dissolved electrolytes contained in them, and in normal circumstances a mixture of two samples of water will have a conductivity determined by that of the two samples and the relative amount of each contained in the mixture. Thus, if the conductivity of two confluent waters and that of the resulting mixture are known, it is a simple matter to calculate the relative amounts of water supplied by the two streams.

Calculated values for the percentage of Lake Albert water contained in samples of water from Pakwach on the Albert Nile are given in Table 1. These values indicate that at times the amount of Lake Albert water in the Albert Nile may be as high as 40 per cent and at other times as low as 8 per cent. For the purpose of these calculations the conductivity of the water at Fajao was taken to be 110 units and that of Lake Albert water 720 units. In order to test the validity of the calculations for the percentage content of Lake Albert and Victoria Nile water in the Albert Nile, appropriate mixtures of these two waters were made and the conductivity of these mixtures measured. In all cases the calculated values agreed with the actual values.

For many years estimates[1] have been made of the discharge of water at Fajao and of the amount of water flowing down the Albert Nile. These estimates indicate that the amount of water flowing down the Albert Nile is on the average about 10 per cent more than the flow at Fajao. Although the discharge at Fajao can be measured reasonably accurately, it is, unfortunately, impossible to measure the flow down the Albert Nile with the same degree of accuracy, because the banks of this river are deeply overgrown with papyrus. Considerable quantities of water no doubt flow through this fringing belt of swamp vegetation, but it must be nearly impossible to determine how much. In the circumstances, it would seem to be advisable to consider with some reserve the recorded rates of discharge down the Albert Nile.

The question of how much water in the Albert Nile is derived from the Victoria Nile and how much from Lake Albert has not previously received close attention. The Victoria Nile has usually been considered as a tributary flowing into Lake Albert, without regard to the fact that it enters the Lake so close to the outlet that, as shown above, most of its water passes straight into the Albert Nile. Whether the waters of the Victoria Nile flow directly into the Albert Nile or not may at first appear to be a point of academic interest. However, as it is difficult to estimate accurately the flow in the Albert Nile, any information that may help towards obtaining a more accurate estimate is worth considering.

Although it is not possible to say that all the Victoria Nile water flows directly into the Albert Nile it seems, from the evidence available, that more than 90 per cent of the discharge at Fajao does so. It thus appears that by using the known discharge at Fajao and the conductivity values recorded at Pakwach, an approximate estimate of the amount of water flowing down the Albert Nile could be obtained. This estimate may be at least as, if not more, accurate than the direct measurements made at Pakwach. At a later date it is hoped with the co-operation of the Uganda Hydrological Survey Department and the Egyptian Ministry of Public Works to go into this matter in greater detail.

Apart from the above considerations, records of the conductivity of the water at Pakwach could be of value for other reasons. It can be seen that over quite short periods of time values for conductivity may vary considerably; these fluctuations could be used to estimate the time taken for water to travel downstream, probably at least as far as Bor in the Sudan. J. F. Talling, of the University of Khartoum (*in litt.*), has noted that marked fluctuations occur in the conductivity and chemical composition of the water in the neighbourhood of Bor; he tentatively explained these fluctuations as due to changes in the contribution of water derived from Lake Albert.

In a memorandum[2] addressed to a Commission to consider the question of the salinity of Lake Albert and its bearing on irrigation, H. E. Hurst stated that the proposed regulation of Lake Albert by means of a barrage at Mutir, some miles below Pakwach, would not increase the salinity of the summer water supply to Egypt by an amount which could damage either the cultivation or the land. This may indeed be so, but Hurst assumes that under the new conditions all the water from the Victoria Nile will, as at present, find its way into the Albert Nile. However, the possibility exists that raising the level o Lake Albert may have a very significant effect o the fate of Victoria Nile water. At present this wate travels through more than a right angle in order t reach the outlet of the Lake; it seems that the flo of Lake Albert water across the mouth of the Victori Nile delta brings this about. This deflexion of th Victoria Nile water is no doubt further assisted b the way the delta has been formed.

If the level of Lake Albert is raised, the effect o existing channels in the delta will be largely abolishe and the velocity of the outflow from Lake Alber will be reduced. At present the depth of water acros the outlet is slight. At one point in the channel use by the lake steamer the maximum depth is onl three metres. Raising the Lake by only two metre would reduce the velocity of the outflowing curren very considerably; this current might then not b sufficient to deflect the Victoria Nile waters toward the outlet. The consequence of this would be t allow more Victoria Nile water to flow into Lak Albert. Thus, the outlet from Lake Albert might i the future come to consist mainly of typical Lak Albert water. The introduction of large amounts o Victoria Nile water into Lake Albert and the withdrawal of typical Lake Albert water might have very profound effect on the biology of the Lake b causing a reduction in its salt content and perhap bringing about a reduction in fertility. It is als possible that the new conditions might favour th development of thermal stratification and thus caus great changes in its biological economy. These idea are at the moment rather speculative, but it is hel that more hydrological data should be collected befo proceeding with plans to build a barrage at Mutir.

In the memorandum quoted above, Hurst state that the Semliki River has a salt concentration th same as that of Lake Albert. The data contained i Fig. 1 show that the salt concentration varies ver considerably and is only the same as that of Lak Albert occasionally. These fluctuations in the sa content of the waters of the Semliki merit furthe consideration. They are undoubtedly brought abo by varying amounts of water received from strea running off Mt. Ruwenzori. Unfortunately, there a not adequate data available on the electrical conductivity of these streams to permit an accura estimate to be made of the amount of water receive from these sources. Some samples of water ha been obtained from these rivers; they contain a lo concentration of dissolved salts and their electric conductivity is about 40 units. However, as only few streams have been sampled, no reliable avera value can be given; but if it is assumed that a average value of about 40 units is probable, it appea that at times more than half the water entering La Albert by way of the Semliki is derived from M Ruwenzori.

The Semliki is a large river and certainly influenc the flora and fauna of Lake Albert, both on accou of its chemical composition and its temperatur The chemical and physical condition of this water determined by the relative amounts of water receiv from Lake Edward and from Ruwenzori.

Lake Edward should be considered as contributi significant quantities of dissolved salts to La Albert, and at times plant nutrients which affect t fertility of this lake. The amount of these pla nutrients in the outflowing water at Ishango depen on the hydrological conditions obtaining in La Edward at the time. Lake Edward becomes thermal stratified for considerable periods; at such times plant nutrients in the surface waters are reduced to very low values. However, when thermal stratification is broken down and water from the deeper layers is brought to the surface, high concentrations of nutrient salts are found in this water. It has been shown[3] that in the waters of East Africa sulphates are frequently in short supply; they may therefore be used as a suitable and convenient chemical label or indicator of the potential fertility of the water. At those times when Lake Edward is thermally stratified, sulphates are reduced to one or two parts per million; but after 'turn over', values as high as one hundred and twenty parts per million have been recorded.

It is probable that significant amounts of certain plant nutrients, such as phosphates, are supplied to Lake Albert by the water derived from the Ruwenzoris, but there are few adequate observations on this.

There is little doubt that the water from the Ruwenzori streams is colder than the water from Lake Edward, and that at those times when the Semliki contains a high proportion of water from Ruwenzori, it will be at a lower temperature than when more of the water is derived from Lake Edward. Further observations need to be made, but it seems that the influx of this cooler water into Lake Albert may explain the periodic mortalities of Nile perch in this Lake. This water may be expected to flow into Lake Albert beneath the surface and, while flowing along the bottom of the Lake in contact with the warmer bottom deposits, may become deoxygenated. Fish swimming into this water are likely to be asphyxiated. This hypothesis is discussed in a paper by Fish[4] on the oxygen requirements of certain fish.

It is submitted that further hydrological data collected on the head-waters of the White Nile should include records of the electrical conductivity of the waters of the Semliki and the Albert Nile, as these observations are likely to add considerably to our understanding of the biology of Lake Albert and may also be of great importance with regard to projects aimed at making greater use of these waters for irrigation in the Sudan and Egypt.

OBITUARIES

Mr. L. Bainbridge-Bell

Labouchère Bainbridge-Bell, who died on August 7, interrupted his education at Emanuel College, Cambridge, in 1914 to join the Signals Branch of the Royal Engineers and won the Military Cross in the battle of the Somme. Later he served in Egypt as a wireless officer in the R.F.C. and R.A.F. After demobilization, he spent six years with the Radio Communication Co., and in 1927 joined the Radio Research Station, Slough. In 1935 he became one of the group of scientists working, under the direction of R. A. (now Sir Robert) Watson-Watt, on what is now known as radar. For his part in this development he received an award of £2,400 from the Royal Commission on Awards to Inventors, and it was characteristic of Bainbridge-Bell that he immediately gave the money to charity.

In the first week of the Second World War he was seconded to H.M. Signal School at Portsmouth and shortly afterwards flew to Montevideo, when the German battleship *Graf Spee* was scuttled in the River Plate; after many adventures, he was able to confirm that the enemy was using shipborne radar, and he returned to Britain with invaluable details of the equipment.

After the War, Bainbridge-Bell re-organized the arrangements at the Admiralty Signals Research Establishment for producing technical reports, establishing a system of centralized editing which not only relieved harassed laboratory workers of much paper work but also ensured uniformity of layout, presentation and illustration. He represented the Admiralty on the Glossaries and Symbols Panel of the Armed Services and was also a member of the British Standards Institution committees dealing with graphical symbols and with the glossary of terms used in telecommunications. It was mostly due to his efforts that the Services standard of graphical symbols and the British Standard were each modified so that they became identical, with the logical next step that the Services could cease a separate publication and use the British Standard. Bainbridge-Bell retired from the Royal Naval Scientific Service in August 1953, on reaching the age of sixty, joined the British Standards Institution and became secretary of the committees on which he had served as a member for many years.

Bainbridge-Bell was one of the few men who have combined science with classical scholarship and hence was most valuable on a committee dealing with the definitions of technical terms. At times, his ruthless exposure of false or incomplete reasoning, of lack of precision, or of attempted concealment of ignorance by verbosity, could be embarrassing. Yet he was essentially kind and had the respect and regard of numerous friends for his tremendous energy and enthusiasm.

J. Reading

Mr. J. W. Lester

John Withers Lester, whose death at the untimely age of forty-seven occurred on August 9, was born in Walsall, Staffs, in 1908 and was educated at Wrekin College where, besides taking a prominent part in Rugby football and boxing, he devoted much of his spare time to natural history, either in the field or in reading books on the subject. In fact, from a very early age he displayed an interest in animals, particularly reptiles and amphibians, and even when only five had acquired a sure skill in catching them. This strong interest his parents wisely encouraged, and when during his later school-days the family moved to Cornwall, Jack, as he was known to all, continued his field excursions, becoming in particular very skilled in the hunting of badgers. His early career was with the Bank of British West Africa, and during his six years in Sierra Leone he devoted much of his spare time and energy to collecting animals of all kinds. He sent home many interesting specimens to several zoos, especially that at Primley, Devon, owned by the late Herbert Whitley, and when he resigned from the Bank on his marriage in 1936, he became actively associated with the Primley Zoo, being responsible for the building up of the reptile and tropical house there.

During the Second World War, Lester was an officer in the R.A.F., and then in 1946 he was appointed curator of reptiles at the London Zoological Gardens, where it soon became evident that he was the right man for the job. During the next few years he made several trips to West and East Africa on behalf of the Zoological Society, collecting and bringing back many specimens of mammals, birds and insects, as well as reptiles and amphibians, of interest and rarity. In 1954 he led an expedition to Sierra Leone in conjunction with the B.B.C. Television Service, the outcome of which was the greatly appreciated television series "Zoo Quest", and last year he led a second such expedition to British Guiana.

In January last he was awarded the Zoological Society's Silver Medal. He was a founder-member of the British Herpetological Society.

Throughout his years at the Reptile House of the London Zoo, Lester was unstinting of the time he gave to advising visitors on the care of reptiles, as well as to giving evening lectures to schools and many small societies, and he was always keen to encourage the growth of natural history interests in the young. He made many broadcasts and television appearances. A man of charming, yet unassuming personality, always so willing to share his love of natural history and to help others to that end, his death is a sad loss to his many friends, both at home and overseas as well as to the Zoological Society.

L. C. Bushby

NEWS and VIEWS

Astronomical Society of South Africa: Gill Medal

The Astronomical Society of South Africa announces the first award of the newly established Gill Medal to Dr. Harold Knox-Shaw, "For outstanding services to Astronomy and in particular to South African Astronomy in the successful establishment of the 74-inch Radcliffe Reflector at Pretoria". The Gill Medal commemorates the work of Sir David Gill, one of the most distinguished scientists to work in Southern Africa. Gill was H.M. Astronomer at the Cape during 1879–1907, and is celebrated for his numerous contributions to astronomy, notably his determination of the solar parallax, his leading part in the introduction of photography into astronomy, and his design of the Cape Transit Circle, a model for many later instruments. The Medal, which is in silver, of a diameter of two inches, bears on the obverse a portrait of Gill in low relief, and on the reverse, a representation of Gill's favourite instrument, the 7-in. heliometer. On the same face is the inscription—"Awarded for services to astronomy". The Gill Medal is probably unique among honorary awards by scientific societies in that it was designed by a president of the Society during his year of office, for Dr. Peter Kirchhoff of Johannesburg, the well-known sculptor, is also a keen amateur astronomer, and executed the design during his presidential year. The medal is to be awarded not more than once in any year for services to astronomy, preference being given to services to astronomy in Southern Africa.

Dr. H. Knox-Shaw

Dr. Knox-Shaw was educated at Wellington and Trinity College, Cambridge. He began his astronomical career in 1908 as an assistant at the Helwan Observatory in Egypt. He took charge of the newly installed 30-in. Reynolds reflector and used it to photograph southern nebulæ as far as south declination 40°. In addition to purely astronomical work, his duties covered the usual scope of a government observatory—time service, gravity survey, geodesy, meteorology and the like. In 1913 Knox-Shaw was made director of the Helwan Observatory, and in 1918 also of the Meteorological Service of Egypt and the Sudan. In 1924 he returned to England to become Radcliffe Observer at Oxford. Two pieces of research in this period are especially noteworthy: the determination of the proper motions of more than 30,000 faint stars in the northern selected areas, and the reduction (in collaboration with Dr. J. Jackson) of the meridian observations of Thomas Hornsby, the first Radcliffe Observer, made between 1774 and 1798. The latter part of Knox-Shaw's term of office as Radcliffe Observer was concerned with the transfer of the Observatory to Pretoria, Union of South Africa, and the erection there of the 74-in. reflecting telescope. This change was successfully carried out in face of a long series of obstacles and delays. Knox-Shaw was president of the Astronomical Society of South Africa during 1941–42, and of the Royal Astronomical Society during 1931–33.

Scientific and Technological Man-power in the United States and the U.S.S.R.

Estimates issued by the National Science Foundation, Washington, D.C., on August 3 give the number of graduates in scientific fields in the United States in 1955 as 59,000, or about 20 per cent of those obtaining first degrees, compared with 126,000 in the

U.S.S.R., or 49 per cent of the total graduates; 22,600 of the former and 59,000 of the latter were in engineering, 2,000 of those in the U.S.S.R. being agricultural engineers. The total number of living graduates with first-level degrees, or their equivalent, in the United States is given as 1,536,000, of whom 575,000 are engineers, and 1,158,000 (555,000 engineers) in the U.S.S.R. In the United States there were, in 1955, 114,600 living Ph.D.s, including 61,800 in science and engineering, and 1,360,000 teachers, of whom 181,000 were working in higher educational establishments, and 130,000–140,000 were teaching science and mathematics in high school. The U.S.S.R. had 80,000–85,000 living persons of Ph.D. level and 9,000–9,500 with advanced doctor's degrees, of whom 60,000–68,000 and 6,000–7,000, respectively, were in science, and 1,900,000 teachers at all levels (120,000 in higher educational establishments and 350,000 science teachers in secondary schools). In the United States 2,721,000 students were enrolled in institutions of higher education and 287,000 first degrees were conferred, of which 9,050 were in biological science, 10,516 in physical science, 7,170 in agriculture and 22,589 in engineering. In the U.S.S.R., 1,865,000 students were enrolled at higher educational establishments, and 265,000 graduated at a level equivalent to a first degree in the United States. Of live holders of first degrees, 566,000 were in engineering and 205,000 in agriculture, 240,000 were science teachers and 87,000 were university graduates in science. Dr. A. J. Waterman, commenting on the danger of making comparisons, except in very broad terms, points out that while in the United States graduates in science may not necessarily be employed in the field in which they were trained, in the Soviet Union they are likely to be so employed.

Employment of Coloured Workers in the Birmingham Area

The report of an inquiry initiated by the Birmingham Christian Social Council and undertaken by the Race Relations Group of Fircroft College, Birmingham, into the employment of coloured workers in the Birmingham area, has been published by the Institute of Personnel Management as Occasional Paper No. 10 (pp. 30; 1956; 3*s*. 6*d*.). The inquiry was conducted between May 1954 and July 1955, thirty-five places of employment, covering ninety thousand employees and 2,150 coloured workers, being visited. The report, which is written by Leslie Stephens, deals with the background of coloured workers in Britain, including the reasons which bring them here, and whether they are likely to stay, and discusses national differences between West Indians, West Africans and Pakistanis. There are chapters on employment policies, the attitudes of trade unions and British workers, and on the attitudes of coloured workers themselves. Its concluding chapter, which stresses the need for a good deal more information on the actual experiences of coloured workers at work and in trade unions, suggests that the conditions revealed by the inquiry do not give grounds for very grave concern and contain many hopeful elements, although there is undoubtedly some discrimination in the relations of employers and workers to coloured people. Concrete recommendations include the preparation of something in the nature of a Code of Fair Employment for coloured workers or for immigrants in general. More advice should be available to potential employers of coloured workers, and every effort should be made, particularly in the countries of origin, to press on coloured workers their own responsibilities. In every town with appreciable numbers of coloured workers there should be an officer like the liaison officer in the Town Clerk's Department in the City of Birmingham, and an advisory committee with a special concern for the welfare of coloured workers; to increase the effectiveness and raise the level of work of local authorities and voluntary bodies, the Home Office or Colonial Office should be given an overall responsibility for the welfare of coloured people and other immigrants in Great Britain.

Nok Culture of West Africa

The July issue of *Man* contains a striking illustration of a life-size terra-cotta head in the now familiar Nok style. Bernard Fagg, curator of the museum at Jos, describes the find, which was made in the course of tin mining at Nok itself in southern Zaria Province, Northern Nigeria. The Nok culture is now known to stretch approximately three hundred miles across the Benue-Niger valley from Katsina Ala in Benue Province to Kagara in Niger Province. These artists have made heads that are more beautiful, but few that are as striking as the one here discussed. It must have needed great skill to fire such a large piece with the primitive means at their disposal. The thickness (just under ½ in.) is uniform, and on the top of the head are five bosses probably representing coiled hair. Four of them are pierced, perhaps for the insertion of feathers. Bernard Fagg suggests a date in the first millennium B.C.; but until definite proof from carbon-14 dating comes to hand, there seems little reason why a considerably more recent date might not be postulated.

Underground Storage of Grain

Primitive methods of the storage of grain in underground pits have been practised in the Middle East for many centuries; but not until 1942, when an experimental underground store was built in the Argentine, was any attempt made to develop the idea along scientific lines. These first trials proved highly successful, and, in spite of the hot and moderately damp climate in which they were carried out, wheat and maize remained in excellent condition for up to seven years. The method has been adopted on quite a large scale in several South American countries, the Argentine now having storage for some two million tons of grain. The possible value of similar systems in British Colonial territories has been under investigation during the past three years, and the results of the inquiry are published in a Colonial Office pamphlet, "Underground Storage of Grain" (Colonial Research Studies No. 21. Pp. 27. London: H.M.S.O., 1956; 2*s*. 6*d*. net). Considerable success has been achieved, and it is hoped to construct pit storage for 11,000 tons in Tanganyika and for 10,000 tons in Cyprus in 1956. The efficiency of underground storage systems depends on the fact that virtually air-tight conditions are achieved. Oxygen is sufficiently depleted, and enough carbon dioxide is produced to inhibit further insect development, and often to kill any insects that may be present. No heating of the grain occurs, and external changes of temperature are unimportant owing to the structure of the pit and the large bulk of grain stored. The method has proved cheap and efficient provided the grain is dry (less than 13 per cent moisture), and can now be recommended for the storage of both maize and wheat.

Systematics of the Notostraca

THE Notostraca constitute an order of the Euphyllopod Crustacea that is interesting not only because they are examples of primitive Crustacea but also because of their adaptation to life in temporary pools and practically world-wide distribution, and in "A Review of the Notostraca" (*Bull. Brit. Mus.* (*Nat. Hist.*), 3, No. 1; 1955. Pp. 57; 12*s.* 6*d.*) Alan R. Longhurst has carried out a detailed revision. Careful study of a large amount of material from different countries and museums and from populations reared in the laboratory has shown that a number of the characters that have been used for the erection of species are, in fact, due to differences of age, sex and the number of body segments and appendages as well as the variations that occur naturally in large populations. Only two genera, *Triops* (Apus) and *Lepidurus*, are included in the family and order. Before this revision sixty-nine species and twelve varieties had been included in the order; but Longhurst has reduced that number to nine species and twelve varieties (not the same twelve as previously). The systematic part at the end includes a very clear and straightforward key for the identification of the species of the two genera, and in dealing with each species an indication of the range of variation is given and, where required, the differentiating characters of the varieties. For completeness, this section might have included the name of the family and its definition and definitions of the genera; for example, under *Triops* the only character given is that it is "separable from *Lepidurus* by its lack of a supra-anal plate".

Measurement of High Temperatures by Thermocouples of Noble Metals

THE accurate measurement of high temperatures is a matter of prime importance in many branches of science and technology, and, in particular, the greater control made possible by the use of thermocouples of noble metals has contributed materially to the successful development of improved methods in metallurgical industry and research. An interesting, illustrated survey of methods of high-temperature measurement and of the development of the thermocouple in this connexion is given in a new booklet, entitled "Noble Metal Thermocouples", by H. E. Bennett, which has been issued by Johnson, Matthey and Co., Ltd., of London (pp. 36; 1956). Three topics are dealt with separately: applications of the platinum metal thermocouple, with particular reference to its use in the steel industry; the properties of the platinum-group metals and their alloys; and the principal causes of deterioration of thermocouples under the headings of strain, prolonged heating at high temperatures, and contamination. Various physical properties of the platinum-group metals are listed, together with calibration curves for different kinds of platinum alloys/platinum thermocouples. Information is included of results of experiments conducted by the author, and there are many references to work of other investigators. A bibliography of forty-nine references is appended.

British Standards Institution: Annual General Meeting

AT the annual general meeting of the British Standards Institution on September 4, it was decided to combine the two formerly separate offices of president and of chairman of the General Council. Sir Herbert Manzoni (City Engineer of Birmingham), who is already chairman of Council, was elected the first president under this new arrangement. He succeeds Sir Roger Duncalfe, chairman of British Glues and Chemicals Ltd., who has served the Institution in many offices for the past twenty years. Mr. John Ryan (vice-chairman of the Metal Box Co., Ltd.) was re-elected vice-president. The following were elected, as representatives of the Institution's divisional councils, to serve on the General Council: *Building Division:* Mr. H. A. Pursey (Turners Asbestos Cement Co., Ltd.); Mr. J. C. Tait (Department of Health for Scotland); and Lieut.-Col. E. Vigor (Neuchatel Asphalte Co., Ltd.); *Chemical Division:* Mr. G. J. Cutbush (Metropolitan Leather Co., Ltd.); Mr. G. Dring (Bakelite, Ltd.); and Sir Knowles Edge (W. Edge and Sons, Ltd.); *Engineering Division:* Mr. P. L. Jones (Swan Hunter and Wigham Richardson, Ltd.); Mr. G. L. Newman (Metropolitan-Vickers Electrical Co., Ltd.); and Mr. B. E. A. Vigers (Laporte Industries, Ltd.); *Textile Division:* Mr. H. N. Aitken (British Celanese, Ltd.); Mr. L. F. Cockroft (John Cockroft and Sons, Ltd.); Mr. P. W. Gaddum (H. T. Gaddum and Co., Ltd.); and Mr. E. R. West (Jute Industries, Ltd.).

National Smoke Abatement Society

THE annual conference of the National Smoke Abatement Society will be held in Southport during October 3–5. The programme will include an address by Mr. Enoch Powell, Parliamentary Secretary to the Minister of Housing and Local Government, on the new Clean Air Act, and a session devoted to the Act from the point of view of local authorities. Other subjects to be discussed are the health aspects of the problem, pollution from road vehicles and problems of increasing the supply of solid smokeless fuels for use in smokeless zones and the new smoke control areas. The Des Voeux Memorial Lecture this year will be given by Sir Hugh Beaver, who will speak on "Clean Air: the Next Step". A resolution authorizing a special general meeting in the near future for the purpose of revising the Society's constitution and changing its name to the "National Clean Air Society" is to be considered. Further information can be obtained from the Society at Palace Chambers, Bridge Street, London, S.W.1.

British Institution of Radio Engineers: Awards

THE British Institution of Radio Engineers has recently awarded the following premiums for papers published in its *Journal* during 1955: *Clerk Maxwell Premium* (the senior premium for the most outstanding paper in the *Journal*), to E. M. Bradley and Dr. D. H. Pringle (the theory and design of gas-discharge microwave attenuators); *Heinrich Hertz Premium*, to Dr. R. Filipowsky (electrical pulse communication systems); *Louis Sterling Premium*, to D. R. Coleman, D. Allanson and B. A. Horlock (the development and design of an underwater television camera); *Marconi Premium*, to Dr. Sin-Pih Fan (the magnetron beam-switching tube: its operation and circuit design criteria); and *Leslie McMichael Premium*, to D. J. Fewings and S. L. Fife (a survey of tuner designs for multi-channel television reception).

Courtaulds' Scientific and Educational Trust Fund: Postgraduate Research Scholarships for 1956

THE Courtaulds' Scientific and Educational Trust Fund has recently announced the award of postgraduate research scholarships for 1956. Scholarships in a branch of science related to the textile, plastics and allied industries (maximum of £400 for one year only, but renewable for further periods) have been awarded to the following: E. W. Abel, Northern Polytechnic, London; Miss P. A. Carr, Imperial College of Science and Technology, London; G. Holden, University of Manchester (renewal); W. A. Keith, The Queen's University, Belfast; and M. T. Pope, University of Oxford (renewal). Postgraduate research scholarships in textile technology, tenable for two years (£320 the first year and £360 the second), have been awarded to the following: B. Chalkley, J. D. Johnson, W. G. Kaye (renewal), A. P. Lockett, D. W. Martin, Miss A. J. Soper, P. E. Williams and E. R. Wyke. The holders of these scholarships have all chosen to do their research at the University of Leeds, except Mr. Lockett, who will work at the Manchester College of Technology.

Oversea Service Division, Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: J. C. Collins (chief tobacco adviser, Northern Rhodesia), senior agricultural officer (tobacco), Uganda; H. A. L. Francis (assistant agricultural superintendent, Dominica), agricultural superintendent, Dominica; J. S. Gunn (agricultural officer, Tanganyika), senior agronomist, West African Institute for Oil Palm Research; R. R. Mason (agricultural officer, Fiji), senior agricultural officer, British Solomon Islands Protectorate; W. V. Rose (deputy director of agriculture, Barbados), assistant director of agriculture, Western Region, Nigeria; Song Thian Siang (senior agricultural assistant, Sarawak), sub-assistant agricultural officer, Sarawak; E. R. Watts (rural education officer, Western Region, Nigeria), agricultural officer, Western Region, Nigeria; A. J. Radford (government chemist, Mauritius), geochemist, Geological Survey Department, Tanganyika; C. W. C. Turner (vice-principal) and J. R. Scobie (lecturer in mathematics), to be principal and vice-principal respectively of the Yaba Technical Institute, Federation of Nigeria; R. J. Dewar (assistant conservator of forests, Nyasaland), deputy conservator of forests, Nyasaland; J. S. Smith (conservator of forests, grade A, Federation of Malaya), deputy director of forestry, Federation of Malaya; R. C. Pargeter (senior geologist, Geological Survey Department, Uganda), senior geologist, Geological Survey Department, Federation of Nigeria; Dr. T. Wilson (senior medical research officer, Federation of Malaya), director of the Institute for Medical Research, Federation of Malaya; R. Mather (meteorological officer, Malayan Meteorological Service, Singapore), assistant director, Malayan Meteorological Service, Singapore; J. B. D. Robinson (scientific officer, Kenya), senior scientific officer, Kenya; J. D. Bald (assistant surveyor, Forest Department, Kenya), staff surveyor, Forest Department, Kenya; B. N. Bowden, specialist officer (ecologist), Northern Region, Nigeria; L. H. Collett, soil conservation officer, Barbados; R. I. Green, agricultural officer (soil conservation), Nyasaland; J. F. Harrop, soil survey officer, Uganda; T. G. Stephen, agricultural officer, Gold Coast; P. Blasdale, entomologist, Tsetse Control, Northern Region, Nigeria; C. A. R. Savory, biologist (game officer), Northern Rhodesia; D. Adair, chemist, Leeward Islands; W. R. Day, forest pathologist, Cyprus; F. Endean and K. A. Jenkins, assistant conservators of forests, Northern Rhodesia; J. F. Harris, geologist (mining), Geological Survey Department, Tanganyika; W. A. Fairburn and D. J. Jennings, geologists, Kenya; S. L. Edwards, statistician, East Africa High Commission; J. G. Hare, veterinary officer, Kenya.

Announcements

AT the annual general meeting of the Manchester Literary and Philosophical Society the following officers were elected: *President*, Dr. F. C. Toy; *Vice-Presidents*, Miss A. C. Alexander, Sir Geoffrey Jefferson, Prof. J. Kenner, Dr. Norman Smith; *Hon. Secretaries*, Dr. L. Cohen and F. Willett; *Hon. Treasurer*, H. Hayhurst; *Hon. Librarians*, Dr. W. H. Brindley and P. G. Lucas; *Hon. Curator*, N. G. C. Pearson.

A SYMPOSIUM on the "Direction of Research Establishments" is to be held at the National Physical Laboratory, Teddington, during September 26–29. Among the speakers will be the directors of research establishments in Holland, Western Germany, Canada and the United States as well as Great Britain. Papers and summaries of the discussions are to be published as soon as possible by H.M. Stationery Office. Further particulars about the symposium can be obtained from the Secretary, Department of Scientific and Industrial Research, Charles House, 5–11 Regent Street, London, S.W.1.

WITH the current year, the *Bibliography of Scientific Publications of South and South-East Asia* is being issued as a priced publication, the annual subscription for four quarterly numbers, of which that for April 1956 is No. 1 of Vol. 2, being Rs. 10. The 1955 volume is also being issued as a single number at the same price. An author index is included with each quarterly part.

THE National Institute of Technology, Rio de Janeiro, has published the first part of a "Bibliografia Brasileira de Química Tecnológica" (1, No. 1; 1954; pp. 153), which has recently been received. It contains references to, and short abstracts of, publications on various branches of chemical technology which have appeared in Brazil during the years 1922–53. These are classified under subjects according to the universal decimal system adopted by the British Standards Institution.

THE Chilean Iodine Educational Bureau (Stone House, Bishopsgate, London, E.C.2) has published a book, "Geochemistry of Iodine" (pp. 150; n.p.), which contains an annotated bibliography from 1825 to 1954 and covers publications on the occurrence of iodine in rocks, minerals and soils, as well as flue dusts, meteorites, iron and steel. The occurrence of iodine in waters and the atmosphere is to be dealt with in a later publication. The book is well arranged and is strongly bound in cloth.

SOLUS-SCHALL, LTD., a firm engaged in the whole field of non-destructive testing, has recently started a "Newsletter" in which brief information is given of new equipment available, new techniques and recent results obtained. Issues will be dispatched free at intervals to all interested. The first number (January 1956) contains brief discussions of the non-destructive testing of welds and of the appropriate spheres of use of X-rays and gamma-rays in industrial radiography. There are numerous half-tone illustrations of apparatus, including an ultrasonic flaw-locating rule, a portable radiation meter suitable for radiation monitoring and as a liquid level gauge, and arrangements for fluorescent X-ray analysis and flash radiography.

APPLIED RESEARCH AND DEVELOPMENT WITHIN THE INDUSTRIAL GROUP OF THE U.K. ATOMIC ENERGY AUTHORITY

By L. ROTHERHAM* and Dr. A. B. McINTOSH†
Industrial Group, U.K. Atomic Energy Authority

WE have previously described[1] the general organization developed for the control of applied research and development within the Industrial Group of the United Kingdom Atomic Energy Authority to provide a development effort for all sanctioned construction projects. The system of organization developed must be integrated with a type of executive management which gives the means of firm direction and control while preserving scientific integrity.

In general terms, the main executive responsibility lies in instituting a type of management which enables a strategic plan of research to be tactically discharged with the necessary standard of scientific and technical excellence. The preparation of appropriate financial and staff estimates, and the maintenance of all records necessary to the forward planning of experimental effort and the periodic reviewing of progress, are essential features.

Allocation of Priorities

The work of the experimental establishments serves both the Engineering and Operations Branches[1]. Broadly, where subject priorities are concerned, it is agreed that existing processes must be kept working before all else; secondly, sanctioned projects must be introduced on time, and thirdly, modifications and refinements recognized as advisable should be added to existing projects as facilities permit. A system of priority classification has been designed to take account of both the subject priority and the latest date before action must be taken by either the Engineering or Operations Branch. Some target dates are irrevocable and must be met; others, if necessary, can be revised as a result of due consideration. Based on an analysis of this sort a decreasing scale of priority can be worked out which introduces the time available for experimental work. Where the importance of the subject justifies it, work required within six months merits the highest priority, for which staff will be made available over all other types of work. The time available for second priority work is arbitrarily fixed, and for third priority work no completion date need be stated.

Some general principle must be accepted for assessing priorities, and those set out above are suitable for some circumstances. The principles must be in conformity with the financial and administrative arrangements, and if this is the case, although they may be arrived at arbitrarily, they can safely be adhered to as a working arrangement. It is useless, however, to have a system of assessing priorities and then to ignore the conclusions reached.

Allocation of Costs

The assessment of priorities provides a convenient method of division into categories so that the costs can be properly allocated.

The cost of development work carried out on behalf of the Operations Branch for the removal of difficulties in, or improvement of, existing processes is borne by the works and recovered as a charge on the finished products. Such investigations, always of a high priority, are undertaken only at the request of, or by agreement with, the works general managers but are never delayed by excessive formality.

The major amount of research and development effort is allocated to work in support of current sanctioned design commitments, and, for such, the charges are borne by the chief engineer of the project. These charges are recovered by an addition to capital charges which are amortized over a period of years. In this category the nature of the problems and the necessary experimental work are discussed thoroughly by the chief engineer, head of the experimental establishment and chief scientist[1], following which an estimate of the cost is returned to the chief engineer without delay so that he can assess whether the cost is in proportion to his need. If he feels that the expenditure is too great and that some engineering solution is both possible and preferable, the nature of the problem will be reconsidered against the general background of reactor development and, if the work is undertaken, it will be as a research and development charge. All long-term research and all work for feasibility and design studies of projects not yet sanctioned are Research and Development Branch[1] charges. Work of this type is carried out by the Research and Development Branch without prior discussion with other branches.

Work Requisition and Initiation Procedure

The implementation of the priority and cost allocation procedure leads to a system of work requisition and initiation designed to ensure that only work is undertaken which is expected to influence the course of development and to prevent the application of effort in directions which, although interesting, would be less profitable. A standard requisition form is the medium by which requests for work are passed from headquarters to the laboratories, or from the laboratories to each other or to headquarters, and copies are sent to any other interested parties. This outlines generally the nature of the problem and gives a brief description of the background to the investigation.

On receipt of the requisition the establishment responsible for meeting the requirements decides the reporting dates, and issues an instruction sheet to appropriate sections. There are cases where reporting dates must be imposed in the requisition to fit in to a programme approved by the Research Board, or to conform to some key design date. In such cases the reason for this is stated in the "Background to the Investigation". If the requisitioned laboratory, in view of its existing commitments, is unable to meet these dates, advice on relative priorities may be obtained from the functional chief scientists, or reference may be made to the Research Board[1].

---

* Director of Research and Development, U.K.A.E.A. (Industrial Group).

† Head of Culcheth Laboratories, U.K.A.E.A. (Industrial Group)

Obviously, any system for requisitioning work or for the initiation of new items of work must not interpose delays. This is avoided by an adequate delegation of authority. The head of each experimental establishment is responsible for the use of his staff. He can start work himself, to a cost of £500–£1,000, without reference to anyone. If larger sums are involved, by discussion with other heads of experimental establishments, chief scientists or the director, work can again be initiated without any formality. Afterwards, instruction sheets, requisitions and cost returns will be prepared. Periodic reviews of progress may also be made to see if the original instructions need amendment.

Planning of Experimental Effort

Accurate planning of scientific and experimental effort ultimately depends on accurate records of effort spent on previous comparable work.

The effort available from each person in a particular period is reckoned as the number of normal working days less an average figure computed from his annual leave allowance and other absences. The number of investigations which can be efficiently worked on decreases as the status of the staff decreases. Excessive diversification is undesirable, and when it occurs the research manager, in consultation with the section leader, decides how many days will be devoted to each job. If the estimates of time allocation are realistic, over-planning indicates that overtime should be temporarily worked, and that for the long term, additional staff or reduction in the number of commitments should be recommended. Conversely, under-planning implies that additional commitments can be accepted or staff can be available for transfer.

The main experimental work must be supported by services from chemical analysis, X-ray crystallography, metallography, etc. The indirect effort involved is more difficult to estimate. When adequate records are available, these will indicate the amount of indirect effort appropriate to the type of investigation involved. To integrate this with the main effort so that the latter is not delayed may present such difficulty that the best solution may be to make an arbitrary allocation of service effort to any particular section, leaving it as the section leader's responsibility to utilize this allocation to meet his priorities.

Staff can only be provided without delay if there is spare capacity, which is rarely the case. Normally all staff are fully occupied and examination is made of the priorities of work in hand to see which jobs can best yield staff to the proposed new one, if this is of higher priority. When this fails, target dates for all work show the earliest date on which staff will be available. New recruitment is regarded as an aspect of long-term planning and seldom enters into decisions related to work to be undertaken in the immediate future. It may be necessary to refer the matter to the Research Board to resolve competing priorities or to agree on alternative measures for obtaining experimental capacity.

Costing of Experimental Work

In the compilation of an instruction sheet, the estimated amount of experimental effort is stated in terms of the grades of staff to be used. Scientific and experimental staff fall into the three categories of senior, main, and assistant grades. Taking an average figure for the salaries of the staff, and a factor computed by the accounts branch from all other normal expenses, the cost of any investigation can be calculated from the instruction sheet. If a second instruction sheet arises from the first, the cost of the second would be an abnormal charge on the first. Similarly, abnormal usage of any particularly expensive item (for example, a rare metal) necessary to some job is clearly indicated on the instruction sheet, so that a particularly heavy charge is carried by the specific job.

The estimates of the scientific effort required for a particular job are compared with the actual returns of effort spent. The basic information is obtained from the sections by weekly returns of the effort of staff against the various jobs. These returns are forwarded to the Accounts Branch and are the basis of the cost figures produced by them relevant to each job on the programme. These cost figures are tabled at each meeting of the Research Board and explanations made of significant deviation from the estimates. The cost of any job is thus currently known at every stage so that its economic value to the project can be kept under constant review.

Management

The management structure of each research and development establishment is similar and is based on definite responsibilities. The success with which an establishment is managed is clearly the responsibility of its head, who is the administrative authority responsible for ensuring that the work conforms to the policy and commitments of the Branch. The management proper of the scientific work falls to research managers, the number of whom varies with the size of laboratory. Generally, each will be responsible for the work of a group of between thirty and forty scientific and experimental workers. The distribution of scientific, engineering and experimental strength varies, depending on the type of work. Where the work has a highly scientific character, the ratio of experimental to scientific workers will approach 1. Where the work is highly repetitive, the ratio may exceed 5 To preserve a career prospect within the scientific class, it is recognized that any number settled as a complement may ultimately reach 50 per cent of the highest grade below that of research manager. To ensure that the earliest possible recognition is given to merit, staff reviews are held twice yearly to a common standard throughout the Authority, at which all eligible staff are considered. The principle of recognizing ability and giving responsibility leads to the early promotion of suitable staff.

The head of the establishment retains the responsibility of ensuring that the method of approach to any problem is selected on valid scientific grounds to yield the information required. It is the research manager's responsibility to see that a high scientific standard is maintained in the laboratories. The head of the establishment, through the planning and progress officer, ensures that the necessary reviews are forthcoming to plan, and that they conform to the required standard.

On receipt of an instruction sheet the section leader must plan his work. The first requirement is to isolate the problem requiring attention, so as to avoid unnecessary investigation. Having first done this and then consulted the literature, he must plan the experimental attack. It is particularly important that he compile an equipment schedule indicating the dates when he requires instruments. All instruments are entered on an equipment register which at any moment indicates the job number on which an instrument is being used and the section where it is located. Any instrument not on a job number must be returned to the equipment store. Only by a procedure of this sort can the best use of instruments be assured within any one of the establishments or throughout the whole branch. For the latter purpose a Branch Equipment Register is held of all plant and equipment in the five Laboratories.

Reporting of Work

All work must be reported in one of the Branch's three recognized documents. The overall general structure and form of reports is agreed at the Research Board and is standardized for the Branch.

A 'technical memorandum' quotes factually the results of experiment and gives no opinions or recommendations. No special vetting procedure is necessary to ensure conformity to policy; but each memorandum must be addressed for the attention of an individual or body whose query prompted the exercise, or who can take any consequent executive action.

A 'technical note' gives the results of an investigation required to settle some point of policy or design. Conclusions are reached and recommendations made to guide further policy or design decisions. All technical notes are addressed for the attention of one of the Authority's recognized committees, or working parties. Technical notes likely to influence the policy of the Branch, either in respect of the prosecution of work within it or of the attitude which it will adopt to some proposal arising from other groups or branches, are addressed for the attention of the Research Board. Because of the influence that any technical note can have on policy or design involving the expenditure of large funds, it is the head of the Establishment's responsibility to ensure that the note has been properly vetted.

A full 'report' has all the requirements of a technical note with the addition that it deals with a completed block of work. It should be of the standard of a paper to a learned society.

The experimental worker is of course responsible for reporting on his own work, but his draft is subject to scrutiny particularly in regard to its general form. The section leader ensures that all experimental facts and observations have been used in the compilation, and the research manager makes any necessary comment as a result of his wider knowledge and experience. Full reports and technical notes before issue are finally approved by the head of the Establishment, who must be responsible ultimately for the quality of work from his own laboratory.

Distribution of all papers is subject to a number of provisions, depending on the status of the document in regard to its classification. The minimum standard distribution is agreed by the Research Board for each type of document, and additional distribution requires special authorization, depending on the category.

Conclusions

Particularly with applied research, the best work is based on the maximum of meticulous observation with scientific analysis of the results. Observations are amenable to timing and therefore to planning. The inspiration so necessary to the forward development comes to those suitably endowed, with or without a declared plan.

Scientific staff may fail to understand the need for, and therefore resent, the passage of paper and forms between one office and another. This is almost invariably a sign of bad management. The forms are not used as a discipline of the scientific staff but as a means of passing necessary information between the various sections which are concerned. Applied research is almost always a team endeavour involving many different skills, and it is a convenience to introduce a measure of formality into the administration, provided it is under broad-minded control. The formal organization of the scheme must not involve the scientific staff in more than a minimum of administrative work, and they should recognize it as reasonable. They must be allowed to make the proper use of their intellectual abilities without the need to digress every few days to consider administration. In each establishment a technical planning officer and administration officer with clerical assistance are quite sufficient to administer a scheme such as has been outlined.

It must be clear that in giving this outline of some of the methods used, we have not attempted to give a full picture. Only an indication has been given of the administrative and financial framework within which the scientific work can be carried out. It is pointless to construct such a framework and then not to use it; but its use must be, on every occasion, conditioned by the thought that the ultimate criterion of success of a research and development department is in the scientific and technical quality of the work done. The scientific staff must feel that the framework is provided to assist them in their work and not to divert them by form filling, committee attendances and so on.

During the period in which the development of the system of organization and management has taken place, opportunity has arisen to observe the reaction of the scientific staff. In general, scientific staff with experience of the system favour the control which it imposes, although about 1 per cent of recruits are unable or unwilling to work when so controlled. The main requirement is that in any establishment the system of organization must be devised by scientists and be acceptable to them.

In the development of this type of organization, responsibility has been given to all members of staff capable of accepting it. This has bred a responsible approach at a remarkably early age.

SOCIETY FOR APPLIED BACTERIOLOGY

SUMMER CONFERENCE

MILK and cheese were the main, but not exclusive, topics discussed at the summer conference of the Society for Applied Bacteriology held in Reading during July 16–18. Several of the papers contributed were by members from the University of Reading and from the National Institute for Research in Dairying, Shinfield.

One of the first papers dealing with milk was by D. J. Williams, J. G. Franklin, Miss H. R. Chapman and L. F. L. Clegg (Shinfield), who described a method for assessing the sporicidal efficiency of ultra-high-temperature sterilization. Membrane filters are used for detecting trace contaminations in the large volumes of milk employed. By adjusting the inoculum of bacterial spores appropriately, this technique allows killing-rates of more than 99·99 per cent to be assessed.

Consideration was given by D. G. Griffiths, R. G. Druce and S. B. Thomas (Aberystwyth) to the present microbiological standards and tolerances for raw milks, some of which, they suggested, should be tightened in view of the continuous improvements taking place in the methods of handling, storing and sampling milks on the farm. They thought that the present methods of testing should be retained, but that satisfactory milks should not have a total count exceeding 20,000 organisms per ml. and the V.R.B. coli-aerogenes content should be less than 10 per ml. J. G. Murray (Belfast) compared the coli-aerogenes test at 30° C. with that at 37°, using raw and pasteurized milks, and obtained no false presumptive results in three thousand samples examined. Of the pasteurized samples examined, 33 per cent were positive at 37°, and 67 per cent were positive at 30° but negative at 37°; of the raw milks, the comparative values were 76 per cent and 24 per cent. Bottles and dairy equipment gave similar results, but not dried milks.

Prof. E. L. Crossley and Miss M. Campling (Reading) described their investigations into the survival of *Staphylococcus aureus* in the production of spray-dried milk, in which they demonstrated undoubted proliferation during bulk storage, but a tendency for a decline in numbers during the evaporation stage. The survival-rates of four strains on spray-drying ranged between 0·25 and 3·5 per cent; such values are inexplicably lower than those reported earlier. It was thought that organisms picked up after the evaporation stage were likely to cause most trouble because of their capacity for selective growth.
